From: John P.
Topic: 18920 Message: 19060

Hi,

  There is a review of this kit at
    http://www.eham.net/reviews/detail/999

   And the item can be found at:
     http://www.hi-rescom.com/html/pdc-1.html

   The price is $27.95 + S&H

  Per the information "installed successfully in Drake, MFJ, Daiwa, Ten Tec, Heathkit and Nye Viking wattmeters (among others!)"

  BTW, I am not affiliated with this business, only sharing information.

Yes. It would be a gread addition as a flat top indicator or preventing

overdrive causing the clipped top waveforms aka flat topping. Did you buy

it as a kit. Is it still for sale?

Generally, I agree.

But, I do want the peak reading feature and I am thinking that by the time

I add the circuit for this feature then the costs will be similar.

I do have the circuit for the peak reading feature addition/mod.

The Heathkit HM-102 is a good SWR/PWR meter. You can find them on eBay for

less than a MFJ will cost you and they really are better.

Subject: [ham-antennas] Re: WTB - Update - HF Wattmeter

Hi all,

I am updated my posting. I am still looking. At this time, and looking at

my budget, I am thinking of the MFJ 815C which has peak reading,

cross-needle, and has 2 ranges including 2KW.

Some here had mentioned a Bird. But this is a little beyond my budget.

I continue to look to buy one in used but good condition.

Thanks,

John - WA2HIP

100' of AWG 18 = 1.30 Ohms. I've never heard of 60' of wire to make a loading coil.

Topic: 18996 Message: 19064

Thanks to all who offered ideas and suggestions about my proposed 10m crossed dipole design. I've decided I will be better off to construct (today) a new dipole and make it manually rotatable. This will solve my problem of directivity.

But now I have another question. I'm going to make the two dipole elements with 3/8" diameter thin walled rigid copper pipes, and I'm going to provide an overhead support with nylon or plastic string to maintain the tubes in almost perfectly horizontal position. I have a feeling the antenna will function better if the elements are perfectly straight and not sagging on the ends. My overall length will be about 16.5 feet. Each element will be about 8.25 feet. However, when I space the two elements apart at the center feed point for connections, then the outer ends are further apart than the 16.5 feet. A 2" gap in the middle results in an overall length of about 16 feet 8 inches. A 4" gap, etc, etc. So, my question is, should the overall length be maintained regardless of the gap between elements at the center feed point? And how does the gap at the center affect it?

You want the overall size of the dipole to be held to the design length. If the ends of the copper have a gap in the middle that will be filled when you spread the center conductor and shield of the coax and attach it to the copper. Also note a little sag of a inch or two won't hurt. You will find as the numbers increase from 10 to 20 or 40 you might find more sagging.

May I suggest you use aluminum, That way you can make it longer and slide it in and out for the best performance
Tell you the truth The measurements are kind of ball park, I always have to trim or shorten to the correct length
and it will be easier to trim to the right length as we all know, once you cut it
Its done.
if you can construct this with copper use the same make the ends slide in or out, That way you can cover more bands if you chose to
I did not see a call sign so I do not know your classification.
I am quite sure some more people have an answer, just my 2 pennies.

Questions have been asked about what is better my 1:1 or the 4:1 balun
The PDF file shows the readings of my 80M size dipole fed with 450 Ohm line
and a 1:1 or a 4:1 balun. Because 10M is so good I might add some 10M half
wave lengths (17'4") to each side and see it I hit some sweet spots on the
lower bands. If I am thinking right a half wave in a antenna is 495/ Freq in
Mhz , it is 468/ Freq when you have the end effect. I am trying to avoid a
half dozen knife switches for different feed lengths. If the PDF can't be
seen please let me know.

19071. Re: DX-CC coils

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-01 17:01:42 UTC
From: alphadeltacom
Topic: 19053 Message: 19071

When it comes to coils and RF, there is no (or little) relationship between DC resistance and inductance/capacitance/reactance (assuming the wire is not so lossy that is has too much DC resistance, which of course these wires don't). Over the length of wire used in the DX-CC coils (69 turns, not feet, 18 ga. enamel) it is normal to show a DC resistance of "short" on a normal VOM. It is actually a few milli-ohms but you won't see it.

The important thing for RF is the inductance of the coil (XL=2πfL) and the interwinding capacitance between the turns (XC=1/2πfC). This combination determines the loading and trapping action of the coils, based on the ham band in use. On 80 meters, the coil is a loading coil for the entire length of wire and on 40 meters, it is an isolating or choking coil for that section.

If sunlight takes off the enamel across the top of the coil wires, it is not a problem. The enamel between turns is what counts and the sun can't get to it. The wires are still insulated from each other There is still enamel on the wire so that even scraping or sun damage across the top of the coils still doesn't "short" across the coils with regard to the reactance/capacitance of the entire coil.

This has been tested many, many times over the 25 years we've been producing this design and there has NEVER been a failure from sun damage. It just doesn't work that way.

I would say the coils are normal and the antenna should work fine if installed properly. If the problem is that the Model SEP static cartridge has failed due to being zapped by a static charge beyond its rating, then that could be a problem and it should be removed. The SEP goes to a short in that case, protecting the equipment until replaced or removed. It is not necessary for the proper operation of the antenna and can be replaced later.

Hope this clears some things up.

When it comes to coils and RF, there is no (or little) relationship between DC resistance and inductance/capacitance/reactance (assuming the wire is not so lossy that is has too much DC resistance, which of course these wires don't). Over the length of wire used in the DX-CC coils (69 turns, not feet, 18 ga. enamel) it is normal to show a DC resistance of "short" on a normal VOM. It is actually a few milli-ohms but you won't see it.

The important thing for RF is the inductance of the coil (XL=2πfL) and the interwinding capacitance between the turns (XC=1/2πfC). This combination determines the loading and trapping action of the coils, based on the ham band in use. On 80 meters, the coil is a loading coil for the entire length of wire and on 40 meters, it is an isolating or choking coil for that section.

If sunlight takes off the enamel across the top of the coil wires, it is not a problem. The enamel between turns is what counts and the sun can't get to it. The wires are still insulated from each other There is still enamel on the wire so that even scraping or sun damage across the top of the coils still doesn't "short" across the coils with regard to the reactance/capacitance of the entire coil.

This has been tested many, many times over the 25 years we've been producing this design and there has NEVER been a failure from sun damage. It just doesn't work that way.

I would say the coils are normal and the antenna should work fine if installed properly. If the problem is that the Model SEP static cartridge has failed due to being zapped by a static charge beyond its rating, then that could be a problem and it should be removed. The SEP goes to a short in that case, protecting the equipment until replaced or removed. It is not necessary for the proper operation of the antenna and can be replaced later.

Hope this clears some things up.

Oops. Sorry for the scramble on the formulas. It must be function of my MacBook. looked OK here. To clarify, XL=2piFL and XC=1/2piFC. I think the "pi" graphic symbol scrambled things.

Properly each half of a dipole is not an element. The entire dipole is an element.
The length of the conductors is what counts, not the overall length.
Why don't you just buy a used 2 element beam?

19075. Capacitor rather than counterpoise for end-fed antenna?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-01 23:43:22 UTC
From: w4phs
Topic: 19075 Message: 19075

I have an antenna question. The easiest way to explain it is to go through my reasoning.

1. With a dipole antenna, the transmitter is an "electron pump" that moves electrons between the two sides of the dipole. Assuming there is no arcing, the same electrons move back and forth on each cycle. During one half-cycle there are extra electrons on one side and fewer on the other, then they flow back to the other side on the next half-cycle.

2. An end-fed antenna has to have a counterpoise. If the counterpoise is a wire laid on the ground under the antenna, it effectively serves as one side of a dipole -- that is, it is an electron reservoir that accepts electrons during the down cycle when electrons are being pulled out of the antenna, and it is an electron source during the up-cycle where electrons are fed back into the antenna.

3. If my view of the counterpoise being a reservoir is correct, then it seems to me that you could replace the counterpoise with a suitable size/voltage capacitor. One side of the capacitor would connect to the transmitter lead (opposite the antenna), and the other side of the capacitor would be grounded. The capacitor would act as the electron reservoir just as the counterpoise did. The capacitor would probably have to be non-polarized. I don't know what capacitance would be required to handle the job.

Is this reasoning correct, or are there other functions that the counterpoise performs besides being a capacitor?

Antennas are tank circuits, but the electron flows goes from end to end, as the energy goes from
inductance to capacitance.

Incorrectly stated, 1/2 of an antenna (1/4 wl) needs a counterpoise to form the other half, a 1/2
wl antenna (an element) holds both polarities (dipole) needs no counterpoise as a center or end fed
antenna.

> 3. If my view of the counterpoise being a reservoir is correct, then it

A dipole is an inductance (the wire) and a capacitor (the two ends of the wire) that resonate
together, a tank. The circuit impedance of the capacitor is extremely high, higher than a foil and
paper device.

> Is this reasoning correct, or are there other functions that the
> counterpoise performs besides being a capacitor?

If the counterpoise is not tuned (way over a 1/4 wl) the counterpoise is a reflector reflecting a
mirror image (reversed) of the 1/4 wl device.

Hi Dean

here is what I have gleaned over the years, the larger the diameter of the element the more broadband the antenna will be (lower Q) however you then have mechanical problems, weight, droop etc. as for the distance between elements well there will be a capacitance effect but I am in the process of making a 15m moxon and I am using a spacing of 1" at feed point, then 16g wire on bamboo frame.

If you want a directional antenna I would look at the moxon, especially as it has a feed point of 50 ohms, have a look at http://www.moxonantennaproject.com/design.htm
very interesting.

If the counterpoise is slowly shrunk from a 1/4 wavelength on down, the capacitive reactance grows larger. You are getting your free capacitance, but the antenna goes out of tune. It needs a larger coil as you shorten the counterpoise, until you have a large coil as the counterpoise. Is this right?????

19083. Re: Capacitor rather than counterpoise for end-fed antenna?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-02 18:01:50 UTC
From: applewiz2000
Topic: 19075 Message: 19083

Hi Phil,

Respectfully - your reasoning is totally wrong because you do not understand how electricity transfers energy. Electrons do NOT race up and down a dipole (or any antenna) when you transmit, or receive for that matter.

You should read "Understanding Electricity and Circuits: What the Text Books Don't Tell You" by Ian Sefton. Here is the link:
http://sydney.edu.au/science/uniserve_science/school/curric/stage6/phys/stw2002/sefton.pdf

I don't know if it's allowed to place a link to that file into Yahoo groups link section?

73s,
Rob
(M0RZF)

From: Larry Tooley
Topic: 19075 Message: 19086

OMG The link remindes me of Electrical Engineering classes which I came to hate. I use the formula the integral of e to the x power is a function of u to the nth power. It reads like this
x n
Se = f (u)

But why did Edisons DC lights at the end appear dim, when on AC they were all the same brightness.

But why did Edisons DC lights at the end appear dim, when on AC they were all the same brightness.

Volt drop; In the AC system you have the advantage of using HV stepped down via transformer to the relatively shorter distribution.

I've never seen a picture of the setup, so don't know if it was done in series or parallel wiring, or even how physically large the layout was, or the insulating materials used. Just a guess, the copper wiring runs voltage drops, with maybe some leakage currents, started to make a significant impact away from the power source. On ac the flow reversed with every half cycle and the brightnesses averaged out. Just a guess....

Adrian, VK4TUX, cleared it up, James. He explained that by using low loss high voltage, power could be transported, then stepped down to 110 VAC for short runs locally. Can't do that with DC. It has to run the whold distance at one voltage.

Again, thank Adrian.

Topic: 19075 Message: 19092

This is the reason why Tesla (AC) beat Edison (DC). Too bad all of the companies weren't named the Consolidated Tesla Company...

Adrian, VK4TUX, cleared it up, James. He explained that by using low loss high voltage, power could be transported, then stepped down to 110 VAC for short runs locally. Can't do that with DC. It has to run the whold distance at one voltage.

Again, thank Adrian.

I've never seen a picture of the setup, so don't know if it was done in series or parallel wiring, or even how physically large the layout was, or the insulating materials used. Just a guess, the copper wiring runs voltage drops, with maybe some leakage currents, started to make a significant impact away from the power source. On ac the flow reversed with every half cycle and the brightnesses averaged out. Just a guess....

OMG The link remindes me of Electrical Engineering classes which I came to

hate. I use the formula the integral of e to the x power is a function of
u

to the nth power. It reads like this

x n

Se = f (u)

But why did Edisons DC lights at the end appear dim, when on AC they were

all the same brightness.

From: dean
Topic: 19075 Message: 19094

Also with AC you can have your power plant many miles away and long runs. With DC you would have to have a lot of power plants all over. Probably one on every block. I remember that from my electronics teacher way back last century.

Now the power company sometimes drops the power (or used to drop the power) lower than 110. With the advent of many computers I think they stopped that practice.

Ok, that makes sense for a large electrical grid... not knowing the circumstances makes for "wags". Don't know much about the early history, but remember Edison as the primary mover for DC and Westinghouse, I think, the promoter of AC in America.

We take all the radios, computers, and other electronics for granted, but parts of the US didn't get electrified until the 30's to 50's time frame. According to Wikipedia, 1.4 billion people in the world still live w/o electricity... they live like our ancestors did for thousands of years. The only light at night is moonlight,stars, and fire.

19099. plastidip

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-04 07:56:43 UTC
From: jo barden
Topic: 19099 Message: 19099

Hi All

Now I know that we should use self amalgamating tape where possible but has anybody tried platidip? was it suitable? just wondering as I at the moment use hot melt glue and no matter how careful I am a "mucky pup" with blobs and small burns to show for it. I was especially thinking of connections to the back of SO 239 etc in boxes to be mounted outside and weatherproofing connections.

Should be great if it sticks. Squirt a blob on a wire. When it dries try to pull it off. Freeze it and try again. Leave it in the sun at 100 deg, and try it again. Let us know, so we can use it. haha

That maybe works for some installations
I also use hot melt glue on some things ... what I do after sealing something is (for better look and better sealing) I reheat the surface or the whole blop with a hot air gun or a lighter ... make my finger wet and make the surface of the glue smooth and even like you do it in the bathroom when applying silicone in the edges .... works fine but wit BIG blops you have to pay attention not to bu your finger (making it very wet helps that glue does not stick at finger ... "outch"
On some parts where sealing should be more flexible silicone works better as hot glue ... and maybe on the parts plastidip could be used
Tell us your results

When TAE first electrified New York he had steam powered generating stations about every 6 blocks , as for the power company lowering the voltage I don't know if they still practice that , however it will not affect computers as they use a DC-DC converter power supply . Switching power supplies will operate from 90 vac to 250vac . 100 volts won't hurt them , it will damage electric motors and until the CFL's came along flourescent lights would not work at 100 volts (from personal experience) . and incandescent lamps would be dimmer than usual , also the old style televisions would not work well at that low voltage . they would have reduced vertical and horizontal scan size and the scan stability would be very critical , again from personal experience , 40 years as a TV repairman . modern televisions and electronics have switching power supplies instead of linear type .

In New York in the late 1800's and early 1900's most of the wiring was underground , just like it is today . The insulation was so bad then that it would not cantain the voltage and you would see horses in certain areas if they were standing still appear to be dancing . they were trying to keep their feet off the street and avoid the electric shock . it is in one of my old reference books that I no longer have , had to leave them behind when I moved . that hurt too . they were useless to the company I worked for (RCA) , the books went back to 1921, but the owner would not sell them and they are probably in a landfill by now .

After seeing this thread I started to look into the Plastidip products.
It appears that they have "Liquid Tape". This might be something that
you are looking for. Haven't tried it but they claim it has good
electrical and environmental insulating properties. I might
consider using it on my R7 after I finish rebuilding it. Needs
further investigating...

I used "Plastidip" back in the early 90's and it seemed pretty
good for tool handles. Did not get tacky (from dirt) and it
cleaned pretty well.

Here's the link:

I use Amazing Goop Automotive contact adhesive and sealant on all open wire and ring terminal coax connections. It seals it and keeps water out of the coax.

You can get it at Walmart.

Brown-outs were common in Greece when I lived there from 1981 to 1983. (I was SV0CE.) One day, my wife called to me, "The TV is a green box." I thought to myself, "What on earth is she talking about?" When I took a look, I saw that the normally-color picture on the TV was a green rectangle about a quarter of the size of the screen. I grabbed my voltmeter and checked the line voltage. There was only 85 volts on the 240 volt line. I quickly unplugged the refrigerator to save the motor.

I put my Deer whistles on the front of my Saturn Vue with hot melt glue. It took about 8 years for one of the two to fall off. Our temp goes from freezing in the winter time to over 120 degrees in the summer time.

Deer whistles are supposed to stop the Deer from running across the road into your car. So far so good.

Hi,

I am going to give the 43' vertical a try with a Icom AH-4 at the base.
I looking at the DX Engineering older style DXE-MBVE-1 or the new DXE-MBVE-5 with the Saf-T-Tilt base.
Has anyone tried the new style, looks like a lot of reviews on the original.
Looking for any opinions or info.

Thanks
Jay N1FDX

For protection of connectors: first a layer of tape and after that a god layer of plastidip
You can sure cut the plastidip later and peel it off if you have a protection layer (tape) between connector and that plastidip coating
But all that is maybe better done with the liquid tape ... should be easier to peel off later ... any testers yet?!?!?

Dg9bfc
Sigi
Ps maybe that is the reason why company makes both ... plastidip for tool and liquid tape for connectors

19115. Inductance/Capacitance meter

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-05 14:52:22 UTC
From: jo barden
Topic: 19115 Message: 19115

Hi All
just thought I would recommend a meter kit I bought, no I am not relative etc. it is PIC based and was £19.90 including delivery, it was from http://s9plus.com/ and marked as CLARA you have to supply wires and box but switches,display and everything else is there, I cocked it up so mailed the person and he gave advise, I sent it back and 2 days later it is in my grubby hands, needless to say my fault but hey good service so I cannot complain.He has a downloadable manual so you can see what is involved before getting which is nice, it is based on the AADE version. I have checked capacitance against my Sparkfun meter and Clara reads 27pf and Sparkfun 30pf, inductance I only have miniature inductors and 150uH showed as 160uH so within tolerance.
Anyway I am a happy bunny, now off to do some filling of box to fit it in.

In New York in the late 1800's and early 1900's most of the wiring was underground , just like it is today . The insulation was so bad then that it would not cantain the voltage and you would see horses in certain areas if they were standing still appear to be dancing . they were trying to keep their feet off the street and avoid the electric shock . it is in one of my old reference books that I no longer have , had to leave them behind when I moved . that hurt too . they were useless to the company I worked for (RCA) , the books went back to 1921, but the owner would not sell them and they are probably in a landfill by now .

I use Amazing Goop Automotive contact adhesive and sealant on all open wire

and ring terminal coax connections. It seals it and keeps water out of the

coax.

You can get it at Walmart.

Amazing Goop Automotive contact adhesive and sealant is for when you strip the ends of a piece of coax and put ring terminals on it, it keeps the water from getting in the coax and it is very hard to remove.

For PL259 and N connectors I use Mocap tape which is self bonding silicone tape and when you need to disassemble the connection you just cut the tape and it comes right off, and the connector looks like you just put it on.

Hope this answers the question, if you need more info just ask.

Have a great day everyone.

Plastidip is really great stuff. I have used it on several things around the house. Two really neat things I have used it on are the bottoms of NATO metal jerry (gas) cans and the plastic grips on one of the pistols I own. It keeps the bottoms of the metal cans from getting scraped up and rusty, and it made the plastic grips on the pistol quite a bit more "grippy"

It is very versatile and useful substance. One of the neat things about it is that it can be thinned. So if you don't want a thick globular coat of rubber on something, you can thin the pastidip, pour it on to give an even coat and bob's your uncle. Their spray cans are pretty neat too, but I have found that they apply a very thin coat and to build up any thickness you need to apply several coats. Therefore the can doesn't go very far.

I could see wrapping a connector in some kind of tape and then spraying it with plastidip. I think it would be about as waterproof as you could get. When it comes time to remove it, just give it a slice with a razor knife.

I've been using PlastiDip and Liquid Electrical Tape for over 10 years now on outdoor coax connections. Liquid Electrical Tape is easier to apply. Anyway, works great - even through our hot Texas summers. And it is easy to peel off when you want to get back to the connector. I use a hobby knife and slice across the coating, then just peel it off.

Topic: 19122 Message: 19122

Hi Group,I have a Hygain HDR300AX which is not reading direction correctly.

When it reads 0 degrees the antenna is pointing north, as the antenna
is rotated the display reads correctly until 140 degrees and then jumps
to 574 degrees and from that point on the display does not change
although the antenna continues to turn ok.

My thoughts are that the 3 turn pot has gone faulty somehow,
although the voltage readings are correct as given in the handbook
for 0,180 and 360 degrees so i wonder if anyone has had any problems
with the controller or any similar symptoms with these rotators?

I would be grateful for any info,Thank you,Mick,MI0GRG.

19124. Counterpoise question for long wire antenna - Question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-08 03:50:55 UTC
From: Will
Topic: 19124 Message: 19124

Quick Question regarding long wire antennas and counterpoise/grounds:

I have cut a length of wire to 35.5 Feet for uses as a non-resonant long wire antenna for portable use with my FT-817.

What length should I use for the counterpoise that will lie on the ground? Should it be the same length of should I cut one that is resonant at each band I am going to operate on?

Thanks for any input:

Will ☐ N7IPY

19125. Random wire and counterpoise

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-08 10:14:49 UTC
From: ninevictor
Topic: 19125 Message: 19125

Hi Will,
Let's call it a random wire. "Long wire" implies a gain type wire antenna that is so long that it is multiple wavelengths and the signal radiating from some parts of the wire reinforce that from other parts of the wire, accomplishing gain.

I am assuming you are going to do without feedline and just hook the antenna to your antenna coupler. The FT-817 is designed to feed a 50 Ohm impedance antennna, so for multiband use, unless you add an antenna coupler between the transceiver and the antenna, your random wire antenna might cover only 2 bands if you are lucky.

To explain further, your transceiver needs to see a 50 Ohm antenna system. That can be :

[1] an antenna (plus feedline) that is designed to present 50 Ohms to the transceiver. A single band doublet or a fan type multiband dipole will work or a trap type multiband dipole will work OR,

[2] you can put an antenna coupler between the transceiver and the feedline. The antenna coupler,, when adjusted right and when operating within its design parameters will transform what it sees on its antenna side to make it look like 50 Ohms on the transceiver side.

In case number [2] above, the feedline between the coupler and the random wire antenna will have significant losses on bands where the antenna itself does not match the impedance of the feedline. This is true unless the feedline is either very short or it is a type that has really low losses even when mismatched. Examples of low loss feedlines are open wire feeders or the large windowed twin lead.

To get back to your question, If you start with the counterpoise of equal length to the wire you have already cut, and put it at equal altitude, it would make a doublet that is resonant near 7 MHz and it will be easy for your coupler to match. You would want to shorten both wires a little if you intend to use it on 40 meters without adding an antenna coupler. If the counterpoise is in the grass, you will have to shorten the counterpoise even further to make it resonant at the same frequency as your elevated antenna hot wire.

About the terminology:
By antenna coupler, I mean what most folks call an antenna tuner.
These come in various flavors and some are specialized for use with the low loss balanced line (called open wire feeders, ladder line, or twin lead)

Here is what a fairly versatile fixed station setup would be for multiband operation: Your transceiver, then a short coax cable to a link coupled balanced antenna coupler, then balanced feedline to the center of a 133 foot long doublet. The coupler could be any of the Z-match type antenna couplers that are available as kits. Expect coverage on all HF bands, 80 through 10. Be prepared to trim some length off of your balanced feeder if there is a favorite band that is difficult for your antenna coupler to match. And no counterpoise is necessary.

I would encourage you to consider building your antenna coupler from parts or a kit. Further, if you purchase some ceramic insulators and some flexible wire, (even #18 speaker wire will do for a temporary experiment), add some windowed twin lead, and you can build an antenna system that will deliver more performance per dollar than a purchased wire antenna.

If you want to keep the portable station antenna system simple, the elevated random wire plus a slightly shorter counterpoise in the grass can serve the purpose. If you build a L type antenna coupler and simply hook your antenna wire directly to the coupler (and the counterpoise directly to the coupler chassis) you should be able to adjust the L network to accomplish a 50 Ohm load to keep the transciever happy. The L network is simple, has no ambiguous multiple settings that might be correct, and handles an extreme range of impedances. The tuning of the L network will be sharp. If you have no luck accomplishing a match, reverse the network so it is transforming in the opposite direction as before. High to low versus low to high impedance. Or, if your antenna plus counterpoise happens to be very close to 50 Ohms, just take the coupler out of the circuit. An antenna system without a feedline, such as the one just described, is radiating RF fairly close to the transceiver and sometimes is troubled with RF in the shack. For an at-home antenna system, you can avoid the RF in the shack by having a system with a feedline that locates the radiating portions of the antenna away from the station.

To answer your question regarding multiple counterpoises, one per band is effective in keeping the station from having RF on the mic, key, and radio chassis. be sure to insulate the far end of the quarter wave counterpoises. Expect the counterpoises to carry RF current and to radiate. Take that into account when locating them.

I look forward to hearing what sort of setup you settle on.

Date: 2011-08-08 21:06:52 UTC
From: Will
Topic: 19125 Message: 19126

Don,

Thanks for taking so much time to reply to my question. Lots of good information.

In reality I am working on 2 'Random' length antenna projects; one for portable use and another for perminent use at home.

In reasurching Random length antennas, I read that it was best to use a non resonant length of wire, and found a chart that suggested a number of lengths that are non-reaonate on the ham bands, 35.5 and 84 (I think) were 2 I was thing of using.

I use a number LDG auto tuners on all my antenna projects needing a tuner so was thinking of using a small 4:1 balan between the tuner and the wire antenna and then the tuner to the FT-817 as a portable solution. Using small sections of LMR-200 or RG58 as feed lines. I was not sure what to use as the counterpoise was all. I will be visiting with my parents soon and they live in the foothills and was going to bring my FT-817 and some antenna ideas to experiment with (I'll bring the MP-1 just incase the wire ideas fail in the field) Out where they live the RF noise level is much lower than at home in the burbs'.

The home antenna is also a problem. I live in an antenna unfriendly neighborhood so I need to keep wires and structures out of sight from the street view. The back yard is large for this area but is to small for long random length antennas. The metal gutters messed up my ideas of wrapping a random length wire antenna around the house. This is the price I paied for a short commute to and from work I guess.

Anyway tonight I hope to be stringing up the 84ish foot wire in a modified inverted L configuration and attaching a few tuned radials to test with. I will then see if the LDG100Pro can tune it or not.

I am also slowly building a MagLoop that should work between 30M - 15M but have not had time to finish it as I have been working on a few after hour paying design projects, currently working on the Vac Variable Cap support structure.

More to follow in a few days and thanks to everyone for the suggestions.

Ah the good ole days. With my old Johnson Challenger, the antenna coupler, or matchbox was built in as the tune and load controls. I could throw any wire out and load it. It may only load half power, but I was on the air. How do we get a single wire allband high gain antenna? Surely we don't have to wait until Heaven.

From: George Kracke
Topic: 19128 Message: 19128

I have a, what appears to be a 440 mhz range "X" beam. It is a flat "X" 12 elements on a 1/2 x 1" boom 2 pcs. elements are 1/4" alum rod attached to the boom via an insulator. The DE is a rectangle with shorting bars and a coax connection. This part is in pc's. Does any one have an idea toward the maker or some info to share to identify this beam? I will be glad to send photos to anyone to help identify.
Thanks 73's
George w2agr

Look here:
http://www.dk3wn.info/antennen.shtml
is is one of these antennas (look at the pics)
rectangle with bars and coax ... that looks like the one that I have seen on
he roof of mike (dk3wn)
maybe it is the right one

Have you considered a wire loop? They generally work better than end-fed wires at low elevations. They are wideband and easily matched across their useful bandwidth.

The coupler could be any of the Z-match type antenna couplers that are available as kits. Expect coverage on all HF bands, 80 through 10. Be prepared to trim some length off of your balanced feeder if there is a favorite band that is difficult for your antenna coupler to match. And no counterpoise is necessary.
> >
> > I would encourage you to consider building your antenna coupler from parts or a kit. Further, if you purchase some ceramic insulators and some flexible wire, (even #18 speaker wire will do for a temporary experiment), add some windowed twin lead, and you can build an antenna system that will deliver more performance per dollar than a purchased wire antenna.
> >
> > If you want to keep the portable station antenna system simple, the elevated random wire plus a slightly shorter counterpoise in the grass can serve the purpose. If you build a L type antenna coupler and simply hook your antenna wire directly to the coupler (and the counterpoise directly to the coupler chassis) you should be able to adjust the L network to accomplish a 50 Ohm load to keep the transciever happy. The L network is simple, has no ambiguous multiple settings that might be correct, and handles an extreme range of impedances. The tuning of the L network will be sharp. If you have no luck accomplishing a match, reverse the network so it is transforming in the opposite direction as before. High to low versus low to high impedance. Or, if your antenna plus counterpoise happens to be very close to 50 Ohms, just take the coupler out of the circuit. An antenna system without a feedline, such as the one just described,

is radiating RF fairly close to the transceiver and sometimes is troubled with RF in the shack. For an at-home antenna system, you can avoid the RF in the shack by having a system with a feedline that locates the radiating portions of the antenna away from the station.
> >
> > To answer your question regarding multiple counterpoises, one per band is effective in keeping the station from having RF on the mic, key, and radio chassis. be sure to insulate the far end of the quarter wave counterpoises. Expect the counterpoises to carry RF current and to radiate. Take that into account when locating them.

Topic: 19125 Message: 19131

I have a friend who has an 80 M loop. He has two 1” long copper pipes attached to each end of the loop. In this case bottom right corner. He has a pair of battery cables attached to his coax and each frequency marked on the pipes. He just comes out of the shack and attach’s it to the frequency he wants to talk on then turns on his Henry amp and talks. No need for a tuner except for the initial tunning.

Did you mean 1 FOOT instead of one INCH? Battery Cables are about 1 inch across on the clamps, so how would the adjustment be made?

19133. Re: Random wire and counterpoise

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-09 16:37:14 UTC
From: Will
Topic: 19125 Message: 19133

Yesterday after work I strung up the 84 foot non-resonant wire in a sort-of inverted L (more inverted U) configuration. Space is limited and the wire must stay close to the house as I don't want to advertise my antenna.

It is end fed, goes up about 10 feet on a small shed then over to the top of a mast that has an anemometer on it, over to a peek on the 2nd floor roof then back down to a short mast at the back corner of the roof at about 12 feet. I put out 1 radial for 40 meters and 1 for 80 meters and went inside to try it.

Using the LDG100Pro it tuned 80, 40, 30, 20 just fine, 1:1 on the LED meter of the LDG. I was able to make WINMOR connections on 80, 40, 30 meters with stations up to 600 miles away, but it is very noisy on 80meters. Next I will add more radials and work on reducing the common mode noise.

> >
> > Here is what a fairly versatile fixed station setup would be for multiband operation: Your transceiver, then a short coax cable to a link coupled balanced antenna coupler, then balanced feedline to the center of a 133 foot long doublet. The coupler could be any of the Z-match type antenna couplers that are available as kits. Expect coverage on all HF bands, 80 through 10. Be prepared to trim some length off of your balanced feeder if there is a favorite band that is difficult for your antenna coupler to match. And no counterpoise is necessary.
> >
> > I would encourage you to consider building your antenna coupler from parts or a kit. Further, if you purchase some ceramic insulators and some flexible wire, (even #18 speaker wire will do for a temporary experiment), add some windowed twin lead, and you can build an antenna system that will deliver more performance per dollar than a

purchased wire antenna.
> >
> > If you want to keep the portable station antenna system simple, the elevated random wire plus a slightly shorter counterpoise in the grass can serve the purpose. If you build a L type antenna coupler and simply hook your antenna wire directly to the coupler (and the counterpoise directly to the coupler chassis) you should be able to adjust the L network to accomplish a 50 Ohm load to keep the transciever happy. The L network is simple, has no ambiguous multiple settings that might be correct, and handles an extreme range of impedances. The tuning of the L network will be sharp. If you have no luck accomplishing a match, reverse the network so it is transforming in the opposite direction as before. High to low versus low to high impedance. Or, if your antenna plus counterpoise happens to be very close to 50 Ohms, just take the coupler out of the circuit. An antenna system without a feedline, such as the one just described, is radiating RF fairly close to the transceiver and sometimes is troubled with RF in the shack. For an at-home antenna system, you can avoid the RF in the shack by having a system with a feedline that locates the radiating portions of the antenna away from the station.
> >
> > To answer your question regarding multiple counterpoises, one per band is effective in keeping the station from having RF on the mic, key, and radio chassis. be sure to insulate the far end of the quarter wave counterpoises. Expect the counterpoises to carry RF current and to radiate. Take that into account when locating them.

Not all battery cables are created equal. I have some that would be hard pressed to connect to a one inch pipe. I did mean one inch. I have never seen a one foot diameter copper pipe. I'd say if you want to do the project then make the pipe fit your battery cables but let me tell you the bigger pipe you use the more expensive it'll be. I did not mean the pipe is one inch long I meant it was about 1 inch in diameter and it was long.

I would have attached pictures but my friend requested I not take any. All I can say is that it is a sweet setup and so simple to erect.

Did you mean 1 FOOT instead of one INCH? Battery Cables are about 1 inch across on the clamps, so how would the adjustment be made?

Apropos of nothing...

Did anyone see the last episode of "Fallen Skies"?

An old-timer figures out that you might be able to jam the alien communications by transmitting on HF. He resurrects an old Globe Scout transmitter and is transmitting during an alien attack on the school where they are hiding.

Deciding they need a "bigger antenna", a helper jumps out the window with a set of battery jumper cables and connects them to a flagpole.

The aliens get confused and run away.

Look here:
http://www.dk3wn.info/antennen.shtml<http://www.dk3wn.info/antennen.shtml>
is is one of these antennas (look at the pics)
rectangle with bars and coax ... that looks like the one that I have seen on
he roof of mike (dk3wn)
maybe it is the right one

W6YL:

You were talking diameter. I was thinking length. Hence the confusion.

19140. Copper vs stainless steel

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-10 17:56:30 UTC
From: Steve
Topic: 19140 Message: 19140

Conductivity of metals
10e6 Seimens/m
Cu. 58
Al. 37
Brass. 16
Ss. 1

I recently noted how low the conductivity of stainless steel is. I use a 9 foot ss whip as the top section of a 20/17 meter vertical. Would the performance of the antenna be noticeably improved by replacing the ss whip with one of copper?

Steve. KD0ETC

19141. RE: [ham-antennas] Copper vs stainless steel

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-10 18:05:57 UTC
From: MIKE DURKIN
Topic: 19140 Message: 19141

I seriously doubt it .... in high current regions of the antenna(base of 1/4wave) , yes, but the loss of SS with such a low current flow compared to Cu might not even be measurable.

If you can get one end up 30' you can make an acceptable half-sloper. How much horizontal room do you have? If you could make a 33' sloper with a tuner at the feedpoint I'd bet it'd be a screamer. Do you have any ground radials?
Dave/kd6il

>
> It is end fed, goes up about 10 feet on a small shed then over to the top of a mast that has an anemometer on it, over to a peek on the 2nd floor roof then back down to a short mast at the back corner of the roof at about 12 feet. I put out 1 radial for 40 meters and 1 for 80 meters and went inside to try it.
>
> Using the LDG100Pro it tuned 80, 40, 30, 20 just fine, 1:1 on the LED meter of the LDG. I was able to make WINMOR connections on 80, 40, 30 meters with stations up to 600 miles away, but it is very noisy on 80meters. Next I will add more radials and work on reducing the common mode noise.

> > In reasurching Random length antennas, I read that it was best to use a non resonant length of wire, and found a chart that suggested a number of lengths that are non-reaonate on the ham bands, 35.5 and 84 (I think) were 2 I was thing of using.
> >
> > I use a number LDG auto tuners on all my antenna projects needing a tuner so was thinking of using a small 4:1 balan between the tuner and the wire antenna and then the tuner to the FT-817 as a portable solution. Using small sections of LMR-200 or RG58 as feed lines. I was not sure what to use as the counterpoise was all. I will be visiting with my parents soon and they live in the foothills and was going to bring my FT-817 and some antenna ideas to experiment with (I'll bring the MP-1 just incase the wire ideas fail in the field) Out where they live the RF noise level is much lower than at home in the burbs'.
> >
> > The home antenna is also a problem. I live in an antenna unfriendly neighborhood so I need to keep wires and structures out of sight from the street view. The back yard is large for this area but is to small for long random length antennas. The metal gutters messed up my ideas of wrapping a random length wire antenna around the house. This is the price I paied for a short commute to and from work I guess.

> >
> > Anyway tonight I hope to be stringing up the 84ish foot wire in a modified inverted L configuration and attaching a few tuned radials to test with. I will then see if the LDG100Pro can tune it or not.

> > >
> > > I am assuming you are going to do without feedline and just hook the antenna to your antenna coupler. The FT-817 is designed to feed a 50 Ohm impedance antennna, so for multiband use, unless you add an antenna coupler between the transceiver and the antenna, your random wire antenna might cover only 2 bands if you are lucky.
> > >
> > > To explain further, your transceiver needs to see a 50 Ohm antenna system. That can be :
> > >
> > > [1] an antenna (plus feedline) that is designed to present 50 Ohms to the transceiver. A single band doublet or a fan type multiband dipole will work or a trap type multiband dipole will work OR,
> > >
> > > [2] you can put an antenna coupler between the transceiver and the feedline. The antenna coupler,, when adjusted right and when operating within its design parameters will transform what it sees on its antenna side to make it look like 50 Ohms on the transceiver side.
> > >
> > > In case number [2] above, the feedline between the coupler and the random wire antenna will have significant losses on bands where the antenna itself does not match the impedance of the feedline. This is true unless the feedline is either very short or it is a type that has really low losses even when mismatched. Examples of low loss feedlines are open wire feeders or the large windowed twin lead.
> > >
> > > To get back to your question, If you start with the counterpoise of equal length to the wire you have already cut, and put it at equal altitude, it would make a doublet that is resonant near 7 MHz and it will be easy for your coupler to match. You would want to shorten both wires a little if you intend to use it on 40 meters without adding an antenna coupler. If the counterpoise is in the grass, you will have to shorten the counterpoise even further to make it resonant at the same frequency as your elevated antenna hot wire.
> > >
> > > About the terminology:
> > > By antenna coupler, I mean what most folks call an antenna tuner.
> > > These come in various flavors and some are specialized for use with the low loss balanced line (called open wire feeders, ladder line, or twin lead)
> > >
> > > Here is what a fairly versatile fixed station setup would be for multiband operation: Your transceiver, then a short

coax cable to a link coupled balanced antenna coupler, then balanced feedline to the center of a 133 foot long doublet. The coupler could be any of the Z-match type antenna couplers that are available as kits. Expect coverage on all HF bands, 80 through 10. Be prepared to trim some length off of your balanced feeder if there is a favorite band that is difficult for your antenna coupler to match. And no counterpoise is necessary.
> > >
> > > I would encourage you to consider building your antenna coupler from parts or a kit. Further, if you purchase some ceramic insulators and some flexible wire, (even #18 speaker wire will do for a temporary experiment), add some windowed twin lead, and you can build an antenna system that will deliver more performance per dollar than a purchased wire antenna.
> > >
> > > If you want to keep the portable station antenna system simple, the elevated random wire plus a slightly shorter counterpoise in the grass can serve the purpose. If you build a L type antenna coupler and simply hook your antenna wire directly to the coupler (and the counterpoise directly to the coupler chassis) you should be able to adjust the L network to accomplish a 50 Ohm load to keep the transciever happy. The L network is simple, has no ambiguous multiple settings that might be correct, and handles an extreme range of impedances. The tuning of the L network will be sharp. If you have no luck accomplishing a match, reverse the network so it is transforming in the opposite direction as before. High to low versus low to high impedance. Or, if your antenna plus counterpoise happens to be very close to 50 Ohms, just take the coupler out of the circuit. An antenna system without a feedline, such as the one just described, is radiating RF fairly close to the transceiver and sometimes is troubled with RF in the shack. For an at-home antenna system, you can avoid the RF in the shack by having a system with a feedline that locates the radiating portions of the antenna away from the station.
> > >
> > > To answer your question regarding multiple counterpoises, one per band is effective in keeping the station from having RF on the mic, key, and radio chassis. be sure to insulate the far end of the quarter wave counterpoises. Expect the counterpoises to carry RF current and to radiate. Take that into account when locating them.

Hello guys. I have a couple questions.

First, a little context on the issues....

I am trying to construct a four element cubical quad for GMRS service. (I know, not exactly ham, but pretend it is for 70cm if you have to... wink wink....)

The main difference between my design and typical quads is that I am not using wire and spreaders for the elements. I am using pieces of bare circuit board material (FR4/fiberglass) with copper tape laid out on them for the "elements". The square boards are drilled in the center so that they can be mounted on a boom made of PVC & nylon.

I can send a picture if anyone wants one.

Ok, my first question: Doesn't the fact that holding the antenna in your hand affect the tuning/SWR? How does one compensate for this?

Secondly, the antenna is designed for 462MHZ. I have swept it using my HT and an SWR meter but haven't found a reading of less than 2:1. I used one of several online calculators to work out the element lengths and spacing. Do you think those values need to be adjusted based upon my construction methods and materials?

Lastly, I have seen descriptions that both require and don't require a balun to feed the driven element. I would rather keep this antenna as simple as possible, so please advise me on whether or not it would be best to implement a balun or whether I can achieve good performance without one.

Thanks
Albert

From: Siegfried Jackstien
Topic: 19144 Message: 19145

The input impedance of a quad has abt 100 ohms (theoretically) so the 1:2 is possible...
The impedance of a quad in a beam antenna can be 50 ohms or even way lower if the elements are close together ....

You can get without a blun with a gamma match (parallel wire on one side with a bridge to the quad and a series cap from center of coax)

The antenna holding in the hand sure effects swr ... so I would either hold it at the back end (make a longer boom and make the handle on the rear end)
Or I would make a short pole (broom-handle or similar) for it

Best thing would be if you would have an analyzer

You absorb power AND you de-tune it.

> Secondly, the antenna is designed for 462MHZ. I have swept it using my HT and an SWR meter but

When elements get close to each other the driven element impedance lowers, like 10 Ohms sometimes, so a stub or gamma/delta matching is necessary.

You must match our feedline to the driven element/s somehow. See antenna books.

The weather finally was a little cooler here. I was able to get outside without melting and got a chance to look at my 2M Slim-Jim antenna at the top of my tilt over. I replaced the 9913 coax with some Belden 8237. For the 50ft run it will be about .3Db more loss with the solid polyethylene but I did not get good readings with a Tektronix dummy load on the end of the 9913. It had a application of CoaxSeal on the antenna end but I guess a few years of rain, snow and ice then sun is not good for 9913. Anybody need some slightly used 9913? I can get it back out of the trash can.

Hi Albert...

Just a thought.... When I first purchased my MFJ259B anntenna analyzer, one of my "experiments" was to connect the 2m rubber duckie from a handlheld. SWR was sky high, and resonance couldn't be found.... unless the antenna was close to the body. So, I guess the answer is "yes", you will have to compensate for the "ground" that the body provides by hand holding the antenna. Exactly how you can accomplish this, especially with a multi-element antenna, I haven't a clue.
Maybe look at an antenna designed for "foxhunting"; might compare calculated design to actual working model.

An inverted "V" antenna is simply a dipole with only one center support.
Because the ends are closer to the ground compared to a common dipole the capacity at the ends will
be greater so it will tune a bit lower in frequency depending on how low to the ground the ends are.

This is not a problem if you loop back 6' of wire at the end insulators and secure the loop with
a "split bolt" at the ends, then you can tune it from the ground. (by loosening the rope or cord)

It's called "old timer's disease." Since you are "inverting" it it will be a bit too long so be
sure to fold the ends back through the end insulators and secure the ends up the wire a bit with
small split bolts. Then you can trim it without soldering, just two small wrenches.

From: Will
Topic: 19125 Message: 19157

Well between an antenna unfriendly neighborhood and a wife that does not want wires hanging around everywhere I have a real challenge. The current stretched inverted U end fed wire antenna is up and working, at least some.

It does tune on 80/40/30/20 to a very low SWR, barly moving the meter on the FT450, but low SWR does not mean the antenna actually works.I only have 3 40M radials and one 80M radial laying on the grass right now. If anything it is a better NVIS antenna than a long range design as it is close to the ground. It does get me on the air so I can have some fun, but the quest to making this a better antenna is on.

Later this year I will be installing a flagpole verticle antenna in the back yard.

Will - N7IPY

>> >
>> > In case number [2] above, the feedline between the coupler and the random wire antenna will have significant losses on bands where the antenna itself does not match the impedance of the feedline. This is true unless the feedline is either very short or it is a type that has really low losses even when mismatched. Examples of low loss feedlines are open wire

feeders or the large windowed twin lead.
>> >
>> > To get back to your question, If you start with the counterpoise of equal length to the wire you have already cut, and put it at equal altitude, it would make a doublet that is resonant near 7 MHz and it will be easy for your coupler to match. You would want to shorten both wires a little if you intend to use it on 40 meters without adding an antenna coupler. If the counterpoise is in the grass, you will have to shorten the counterpoise even further to make it resonant at the same frequency as your elevated antenna hot wire.
>> >
>> > About the terminology:
>> > By antenna coupler, I mean what most folks call an antenna tuner.
>> > These come in various flavors and some are specialized for use with the low loss balanced line (called open wire feeders, ladder line, or twin lead)
>> >
>> > Here is what a fairly versatile fixed station setup would be for multiband operation: Your transceiver, then a short coax cable to a link coupled balanced antenna coupler, then balanced feedline to the center of a 133 foot long doublet. The coupler could be any of the Z-match type antenna couplers that are available as kits. Expect coverage on all HF bands, 80 through 10. Be prepared to trim some length off of your balanced feeder if there is a favorite band that is difficult for your antenna coupler to match. And no counterpoise is necessary.
>> >
>> > I would encourage you to consider building your antenna coupler from parts or a kit. Further, if you purchase some ceramic insulators and some flexible wire, (even #18 speaker wire will do for a temporary experiment), add some windowed twin lead, and you can build an antenna system that will deliver more performance per dollar than a purchased wire antenna.
>> >
>> > If you want to keep the portable station antenna system simple, the elevated random wire plus a slightly shorter counterpoise in the grass can serve the purpose. If you build a L type antenna coupler and simply hook your antenna wire directly to the coupler (and the counterpoise directly to the coupler chassis) you should be able to adjust the L network to accomplish a 50 Ohm load to keep the transciever happy. The L network is simple, has no ambiguous multiple settings that might be correct, and handles an extreme range of impedances. The tuning of the L network will be sharp. If you have no luck accomplishing a match, reverse the network so it is transforming in the opposite direction as before. High to low versus low to high impedance. Or, if your antenna plus counterpoise happens to be very close to 50 Ohms, just take the coupler out of the circuit. An antenna system without a feedline, such as the one just described, is radiating RF fairly
close to the transceiver and sometimes is troubled with RF in the shack. For an at-home antenna system, you can avoid the RF in the shack by having a system with a feedline that locates the radiating portions of the antenna away from the station.
>> >
>> > To answer your question regarding multiple counterpoises, one per band is effective in keeping the station from having RF on the mic, key, and radio chassis. be sure to insulate the far end of the quarter wave counterpoises. Expect the counterpoises to carry RF current and to radiate. Take that into account when locating them.

>
> Elementary question, but I forgot, and can't find a definitive answer in my wire antenna bookÂ

An inverted "V" antenna is simply a dipole with only one center support.
Because the ends are closer to the ground compared to a common dipole the capacity at the ends will
be greater so it will tune a bit lower in frequency depending on how low to the ground the ends are.

This is not a problem if you loop back 6' of wire at the end insulators and secure the loop with
a "split bolt" at the ends, then you can tune it from the ground. (by loosening the rope or cord)

I had measured the wire in meters instead of feet. I could not remember to cut in half (i.e. 20 meters each leg) or if the 40 meters made up one leg (i.e. 80 meter dipole uses 40 meters each leg) Never was very good at math, and add to that the complexity of high tech electronics, well once in a while it causes a short between the headphones :

OCF Carolina Windom for 160 – 10 meters.

I have read a lot on this type antenna.
I have so much to learn about different types of wire antennas.
I want to try as many types that my back yard will hold, I have no restrictions except I have no trees, getting them in the air is my problem, I say a military type fiberglass support pole but is only
30 ft high. I wanted to get at least 40 ft, I cannot afford a tower at this time.
My house is only 25 ft at the highest point. and very accessible, just the air conditioning unit is quite close
 Maybe a tripod would work on top of the house with 15ft fiberglass pole to get that height and away from the AC unit
Any suggestions would be appreciated., Interested in 20 and 40 meters. What is the optimal height I should shoot for;

I have read that you don't have to be a wave length above ground. as low as 11 feet for 20 meters.
Correct me if I am wrong

You can check out my tilt over at the link below
http://s1102.photobucket.com/albums/g453/KD0ZZ/

The tall system is about 40 ft and requires no welding. The 2x3 was cut at the store when I picked it up, cutting was only a dollar.

Rich ,KDØZZ , ☺

from the middle of Missouri , out in the sticks with the hicks and the ticks.

Subject: Re: [ham-antennas] Re: Random wire and counterpoise

OCF Carolina Windom for 160 – 10 meters.

I have read a lot on this type antenna.
I have so much to learn about different types of wire antennas.
I want to try as many types that my back yard will hold, I have no restrictions except I have no trees, getting them in the air is my problem, I say a military type fiberglass support pole but is only
30 ft high. I wanted to get at least 40 ft, I cannot afford a tower at this time.
My house is only 25 ft at the highest point. and very accessible, just the air conditioning unit is quite close
Maybe a tripod would work on top of the house with 15ft fiberglass pole to get that height and away from the AC unit
Any suggestions would be appreciated., Interested in 20 and 40 meters. What is the optimal height I should shoot for;

I have read that you don't have to be a wave length above ground. as low as 11 feet for 20 meters.
Correct me if I am wrong

Topic: 19125 Message: 19165

I went to several web sites on the OCF Carolina Windom.

http://hamcall.net/7bandocf.html

I only visited the one above tonight. I believe you'd want it at least 40 ft. in the air. My inverted V is about 45 ft., its just under my beam antenna.

You could just put up a pole and guy it with a pulley at the top with lots of rope thru the pulley for hauling up the antenna.

I'm like you I have a lot of property but no trees close to the house. Most of my trees are a lot lower than my house. I live in the mountains. Now if I could just talk the wife into letting me put up some poles in the front yard

I'd love to put up a loop but not enough poles to hold it up in the air high enough.

>>> > Here is what a fairly versatile fixed station setup would be for multiband operation: Your transceiver, then a short coax cable to a link coupled balanced antenna coupler, then balanced feedline to the center of a 133 foot long doublet. The coupler could be any of the Z-match type antenna couplers that are available as kits. Expect coverage on all HF bands, 80 through 10. Be prepared to trim some length off of your balanced feeder if there is a favorite band that is difficult for your antenna coupler to match. And no counterpoise is necessary.
>>> >
>>> > I would encourage you to consider building your antenna coupler from parts or a kit. Further, if you purchase some ceramic insulators and some flexible wire, (even #18 speaker wire will do for a temporary experiment), add some windowed twin lead, and you can build an antenna system that will deliver more performance per dollar than a purchased wire antenna.
>>> >
>>> > If you want to keep the portable station antenna system simple, the elevated random wire plus a slightly shorter counterpoise in the grass can serve the purpose. If you build a L type antenna coupler and simply hook your antenna wire directly to the coupler (and the counterpoise directly to the coupler chassis) you should be able to adjust the L network to accomplish a 50 Ohm load to keep the transciever happy. The L network is simple, has no ambiguous multiple settings that might be correct, and handles an extreme range of impedances. The tuning of the L network will be sharp. If you have no luck accomplishing a match, reverse the network so it is transforming in the opposite direction as before. High to low versus low to high impedance. Or, if your antenna plus counterpoise happens to be very close to 50 Ohms, just take the coupler out of the circuit. An antenna system without a feedline, such as the one just described, is radiating RF fairly
>close to the transceiver and sometimes is troubled with RF in the shack. For an at-home antenna system, you can avoid the RF in the shack by having a system with a feedline that

locates the radiating portions of the antenna away from the station.
>>> >
>>> > To answer your question regarding multiple counterpoises, one per band is effective in keeping the station from having RF on the mic, key, and radio chassis. be sure to insulate the far end of the quarter wave counterpoises. Expect the counterpoises to carry RF current and to radiate. Take that into account when locating them.

You have some nice things on there, I especially like the 2 band Dipole
I would like to know more about how that design works.

19167. AW: [ham-antennas] need quick answer

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-12 11:49:54 UTC
From: Siegfried Jackstien
Topic: 19151 Message: 19167

You have just to remember :
A standard dipole is formerly known as HALFWAVE DIPOLE
So 3.5-3.8 >>> 80m BAND >>> 40m DIPOLE >>> 20m each LEG ....
The leg is a QUARTERWAVE length
Greetz
Sigi
Dg9bfc

Ps rule of thump 300 divided by mhz = meters

19168. AW: [ham-antennas] Re: Random wire and counterpoise

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-12 11:58:01 UTC
From: Siegfried Jackstien
Topic: 19125 Message: 19168

A horizontal dipole for 40 has to be high up in the air (min 60 feet) to show a low elevation angle... but if you make a fullzize loop for TOPBAND ... it will even work if it is only 40 to 50 feet high ....
If the loop is very big (and topband loop is big on 40m band!) the elevation angle goes down ....
The effect is a bit like on a longwire ... when fed on higher band and you have more wavelengths on that wire the lobes go more in the direction of the wire instead of 90 degrees like in a dipole

I havw my topband loop only 30-40 feet up ... so I would say : give it a try if you have the room for it
Feed it with ladderline and you have a real multibander with low loss and high gain :-)

19169. RE: [ham-antennas] Re: Random wire and counterpoise

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-12 12:02:37 UTC
From: Richard Schmuke
Topic: 19125 Message: 19169

I suppose you mean 5 band dipole. You can check out “fan” on the net. there are several. Some people say you need to have the ends several feet apart. Well you don’t! The problem you have with the wires close is that a higher frequency wire (short) will interact with a lower frequency (longer). That antenna was made for 75,40,20,17 and 10. The spacers are made from sections of PVC conduit drilled for the wire. Upper wire is 14ga copper-weld and the others just 14ga solid. The 75 was cut by the book but the rest of the wires you need to start a little long and trim to the desired frequency because of the interaction. The antenna is still in use today at Kc0ziu’s place. This was made about 4 years ago, now replaced by a 80M multi band loop and a 135ft doublet.

Rich , KdØzz , ☺

My wife complains I mess with stuff too much but I have a "tinkering virus"

Rich , Kd0zz

You have some nice things on there, I especially like the 2 band Dipole
I would like to know more about how that design works.

19170. Re: AW: [ham-antennas] Re: Random wire and counterpoise

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-12 13:21:23 UTC
From: dean
Topic: 19125 Message: 19170

I been thinking of making a Delta Loop. So I'm looking around the net for ideas of what to use to make the loop more efficient. I read a nice article of a single band delta that the bottom of the loop is only 14 ft. off the ground.

http://w5sdc.net/delta_loop_for_hf.htm

Looks very interesting as I'm looking for one for 17 meters. I have the space to put up a multiple band delta loop. Unfortunately I can't get it higher than 44 ft. off the ground. I can put the apex just below my beam which is about 45 ft. off the ground.

My problem is I don't have any trees close to the house and I sit on decomposed granite and its very hard to dig a hole. So I can use guyed push up poles for the center and tie it off on the house.

Subject: AW: [ham-antennas] Re: Random wire and counterpoise

A horizontal dipole for 40 has to be high up in the air (min 60 feet) to
show a low elevation angle... but if you make a fullzize loop for TOPBAND
... it will even work if it is only 40 to 50 feet high ....
If the loop is very big (and topband loop is big on 40m band!) the elevation
angle goes down ....
The effect is a bit like on a longwire ... when fed on higher band and you
have more wavelengths on that wire the lobes go more in the direction of the
wire instead of 90 degrees like in a dipole

I havw my topband loop only 30-40 feet up ... so I would say : give it a try
if you have the room for it
Feed it with ladderline and you have a real multibander with low loss and
high gain :-)

19171. OOOPS WRONG SIZE

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-12 13:40:54 UTC
From: n8gbu
Topic: 19171 Message: 19171

I put the in the ground (cemented) the o.d. is to big to fit the clamps that fit into the pre-drilled holes on the mounting plate of my M.F.J. 1798 verticle. Any Ideas to fix the problem without digging out the pipe, the pipe has threads on it says its a pump shaft. Any ideas?

thanks in advance mike n8gbu

19172. RE: [ham-antennas] OOOPS WRONG SIZE

From: Richard Schmuke
Topic: 19171 Message: 19172

I took a quick look at the PDF file for the 1798 set up and it should be no problem. One quick fix is to drill some new holes. If you don□t like that, the u-bolts are just ¼-20 , not very stiff, so get some threaded rod and bend you own u-bolt. Grab the threaded rod and bend it around your pipe, bring the legs past parallel then put a dog leg in it to fit the plate.

Rich , Kd0zz

How far are the trees away?
Ever thought of making a BIG LOOP???
Dg9bfc
Sigi
Ps I have a topbandloop here and if I had the room I would double it :-)

Topic: 19125 Message: 19174

Well I have one tree in the front yard about 70 ft. from my radio. Not sure how high it is and forgot my basic math on how to calculate the height of a tree. I know its taller than the house but it's a Chinese Tallow tree and no real high single branch. I have some taller trees about 1 ft from the house but at a much lower elevation. I sit on top of a bluff at about 2250 Ft up. My inverted V fan dipole is 75 M N to S and the 40 meter leg is E to W. I have a very low angle of radiation as 12 ft from the apex of that dipole the ground drops off to sea leval some miles away, SW to W.

I also thought about a pole in the front yard next to the house (of course I would need the wife's permission) and put up a delta loop there.

I thought about putting up a loop over the house, big house. But not too sure about it over my head. The roof is all 2 X 12 boards and the composite shingles over that. In the center of the attic I can stand up my full 6'6" and have a lot more room over my head.

The house is 3500 sq ft.

I'm also 67 years old and disabled so I would have to have some local hams come over and do the work for me. I always get a bunch of steaks and the wife cooks a great meal for them.

How far are the trees away?
Ever thought of making a BIG LOOP???
Dg9bfc
Sigi
Ps I have a topbandloop here and if I had the room I would double it :-)

By the way I was stationed in Kaiserslautern and Mannheim back in 1964 when I was in the Army. It’s a beautiful country.

Sadly the trip to your home is a bit far form e :-)
I would like to build that loop for you :-)
For a steak and some beer *g*
Dg9bfc
Sigi

> copper tape laid out on them for the "elements".

Interesting. What made you go this way? I'd have thought that the
extra weight and air resistance might be detractors, compared to stiff
wire alone.

I think the PC board material will affect the tuning and impedance of
the elements. It makes a higher effective dielectric constant near
each element, so they are electrically longer than their physical
length.

> Doesn't the fact that holding the antenna in your hand affect the
> tuning/SWR?

Somewhat.

> How does one compensate for this?

By trial and error, I suspect.

> I used one of several online calculators to work out the element lengths
> and spacing. Do you think those values need to be adjusted based
> upon my construction methods and materials?

Probably. See above.

> Lastly, I have seen descriptions that both require and don't require a balun
> to feed the driven element.

From what I've seen, a balun for balanced/unbalanced transition may be
desirable, but you can get away without it, if you don't mind some
pattern distortion.

A balun as an impedance matching device, depends on how you feed the
driven element. Some methods give you enough adjustment range so a
separate balun for that purpose isn't needed.

Until you have two supports build yourself a 20 and 40 meter fan dipole and erect it as an inverted "V" and operate.

great news. If your dipole is held up by wire at the ends it shortens the
dipole electrically. Then you use the dipole length formula 468/Freq in mHz

Even greater Larry. I have finally cut the wire (longer than needed, of course), and am about to climb the tower to replace the pulley that come down when last lowered (ha, never have to climb again now that I have pulley system...ya right!) Mother being the power of invention, I found a new center insulator though. I took an old credit card and drilled a hole on each side to hook shield and center conductor to. Then drilled another in middle to act as center insulator. I think it's pretty neat, but time will tell.

Thanks to every one for your input.

Dale K8TS

Hi
My dear friend,I found a very nice website www.xanshop.com, which is holding 10-year anniversaries. It sells notebooks, cell phones, digital cameras with top quality all over the world. The activity is end of 30, June, you will get gifts as long as you registered on it before this time.

Hope you won't miss such a good chance!

Andy,

I am trying to design the cubical quad for UHF (GMRS) field portable operation.

I kind of got the ideas after staring at arrow antennas for a while.

Basically, the "elements" are sandwiched between the threaded sections of pvc. The ends of the pvc have nylon bushings pressed into them that I made on a lathe.

Once disassembled, you have four flat "plates" and four short sections of pvc to stuff in a backpack, plus the coax.

I liked the idea of just buying or building a yagi, but I saw the high possibility of elements getting broken or bent. And of course with the quad you have wire elements which could be a problem.

The 7" square sections of circuit board material (FR4) are quite rigid and tough. You "could" break one but not very easily.

The copper tape is only for the test and design phase of the build. Once I have everything sorted out I am going to etch some copper clad boards so that the traces are permanent.

So that is the method behind the madness.

> great news. If your dipole is held up by wire at the ends it shortens the
> dipole electrically. Then you use the dipole length formula 468/Freq in mHz

Actually, it *lengthens* (not shortens) the dipole's electrical
length. So you need to use a shorter physical length to get the same
electrical length and resonance.

468/F works for your average flat-top dipole, so for an inverted-Vee
you would cut it even shorter (or fold the ends back).

Andy

19190. Antenna Reception Question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-13 20:47:02 UTC
From: radiotech750
Topic: 19190 Message: 19190

I have a Lafayette Ha 600 that I have recently got up and running. I have two antennas that I can use . 1) a 200 foot long wire pointed N/e S/W. 2) a Slinky antenna about 30 feet long pointed E/W The Slinky is in a dipole configuration 15 feet on a side fed to the radio with RG8 mini coax.
My question is... why does the slinky receive better that the long wire? I know there are lots of variables involved, I would think the long would do a better job. The Dipole slinky is also much quieter than the long wire.
I am not an antenna engineer and just asking for ideas why this is so!

From: Andy
Topic: 19190 Message: 19191

> My question is... why does the slinky receive better that the long wire?

Many possible reasons.

Does it happen with several signals from all directions?

What is the height of the long wire? Of the Skinky?

What frequencies?

Is the long wire a dipole or just one wire? If the latter, it is only 1/2 of an antenna; what is the other half? (Ground connection?)

How much feedline?

I don't suggest you need to answer these questions (and don't want to suggest that I could have explanations for you if you did!); they are just factors to consider.

For receiving, even a very poor (inefficient) antenna can be good enough on the MF and HF bands. Efficiency (which matters for transmitting) and output voltage without an impedance matching device (which is what matters for receiving) are two totally different things.

Andy

19192. Re: Antenna Reception Question

Ernie:

First, a word about safety: Follow normal precautions used in servicing, connecting, and operating electrical appliances, antenna systems, and radios. If in doubt, get assistance from someone who has sufficient knowledge and skill.

Antennas for receive are less critical than those used for transmitting. However, for best reception it is worthwhile to make the antenna configuration something like the radio designer intended. Assuming you don't have an owner's manual that suggests antenna styles, we can look at the antenna terminals and learn a bit.
If the antenna connectors on your radio are vastly different from what I describe, please let me know.

Some radios have only a connector for attaching coaxial cable. This can be handy for attaching the feedline to an outdoor shortwave antenna. Or if you want a quick way to attach an indoor temporary scrap of wire which might be a good enough antenna, just put a banana plug on the end of your scrap of wire and plug the banana plug into the center of the coaxial cable connector on the radio. In this configuration, a ground wire will benefit reception.

Hobbyist shortwave radios of the 1960's and earlier usually had a screw type terminal strip for antenna connection.
Here is a generalized description from which you may gain some insight on what to connect and where to connect it. One style of antenna connection was a terminal strip with 3 screws. One screw, identified as "ground" is the place where you could connect a ground wire that runs between the radio and a driven ground rod.

The two remaining screws we will call A1 and A2, are for connecting a balanced antenna feedline of a balanced 200 Ohm impedance antenna. With a pair of terminals provided, you could hook up the slinky dipole and feed it with TV twin lead or a twisted pair of wires or even a piece of two conductor speaker wire. For receiving, if the feedline is only a few feet long, the exact type of wire is usually not very critical.

On some radios, one of the two antenna connection screws, (we will say A2) can accept a jumper wire or bar, connecting it to the ground screw. With that jumper in place, A1 becomes the single terminal where you would connect your random wire antenna. In this configuration, a ground wire will benefit reception.

Somewhere on the front or back of the radio there may be a knob marked "ant. trim" which can be adjusted to help match the antenna to the receiver. This trimmer can usually benefit by being djusted for peak reception whenever you switch from one band to another.

At present, your slinky is an antenna that matches the design of the receiver front end more accurately than the long wire does. That is one reason it out performs the long wire. Add a ground wire and the jumper I mention above and see if the long wire performance improves.

The slinky dipole (a balanced antenna) does not need a ground wire,

That's enough to get you started.
Have fun listening.

I finally figured it out Dave. It is the ratio of Similar Triangles.

Height in inches of stick to the tree Width (inches) of stick to landmark
---
= ---
Height in feet of the tree Width (feet) to landmark

Solving for the unknown:
Height of stick to tree (inches) X
Width to landmark in feet
Height of tree (feet)
= ---
Width of stick to
landmark (inches)

The inches cancel out and giving the height in feet.
Larry WA9G

Sorry but that does not compute.

Use a stick held in front of you, some distance from vertical object, to mark height of tree. Turn marked stick 90 degrees to horizontal. Note landmark where stick mark meets the ground. Measure from vertical object base to landmark.

Actually, it *lengthens* (not shortens) the dipole's electrical length. So you need to use a shorter physical length to get the same electrical length and resonance.

468/F works for your average flat-top dipole, so for an inverted-Vee you would cut it even shorter (or fold the ends back).

Much easier:
Use a stick that is same length of your arm
Hold stick on one end
Stretch your arm horizontal and proof if upper end of stick ends on your shoulder (same length as arm)
Now hold the arm horizontal and the stick vertical (just flip it upwith your hand wrist)
Look with your eyes over upper end of stick
Move backwards (slowly and careful) till stick and upper end of tree match (same line)
Now distance from tree is height of tree
So just walk towards tree and count the steps
Everybody that has cut a tree down knows that

How long is your doublet?

What you are suggesting is not really different than a "fan dipole". As long as the non active elements present a high impedance on the operating frequency, there will be minimal interaction.

19204. WideBand Dipole.

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-15 15:46:13 UTC
From: Joe
Topic: 19204 Message: 19204

OK,

I have done thing many times since I got my ticket in 1975.

Like two dipoles at right angles, say one for 80 and one for 40
connected to a single coax.

Of course it works and works great being the giant wide impedance's one
loads one is ignored depending on what freq being used.

BUT has anyone tried this, or would it even work?

We all know a single dipole will not cover all of 80 meters with a good
match. The percentage of change is just far too much.

But what if you made two 80 meter dipoles. or more accurately described
a 80 meter one and a 75 meter one?

Say minimum swr at 3.6 MHz on one and 3.9 MHz on the other and both
antennas at right angles to each other.

Would this work? would one load better than the other because of the
better match? Are they far enough away from a good resonant match to work?

What happens at the middle of the band where the matches are close to
similar in SWR, but have oppisite reactances? One will be inductive
while the other capacative. hmmmm?

Topic: 19204 Message: 19205

I made a fan dipole that had two dipoles of slightly different lengths, fed with one feedline, but parallel, not perpendicular (so it required fewer anchoring points and took up less space). The wires were a couple of feet apart at the ends. It worked fine. The minimum SWR was not quite as low as with a single dipole at resonance, but the bandwidth was larger.

One design uses elements of the same length, but spread apart at the ends in a bow tie shape. This also broadens the useful bandwidth.

I think it would be better to make it a fan dipole, over and under or side by side.
If you set one to just over one end and the other just under the other end the middle would be not
bad because of the coupling between the two, you would loose that coupling if they were at right angles.

I had a chance to be a lumberjack when I was 21 but I didn't have the correct shoes or corks so I was out of luck. I would have started off as, wow my memory fails me but I would put the cable around the tree so it could be pulled up. Very dangerous job.

Any way I figured I'd get my protractor and make my arm 45 degrees and then when my finger tips hit the top of the tree I then walk towards the tree and then add my height to that distance and I have the height of the tree. I also live on a bluff and there is not much room. I have 8 acres but most of it is a lot lower than my house so not much room to play with. My house is about 12 Ft from one edge of the bluff and in front I got less than 50 ft. to the other edge and the back of the house is close to the mountain and the other side drops off quickly. I live at the highest part of my property. I have a huge barn who's roof is lower than the base of the house and the mobile home at the bottom of the hill is even lower.

So basically I have to put my antennas close to the back of the house or by the end close to the mountain. One bad thing is the corner from the back to the mountain is my power lead from PG &E (our power company).

Now the tree to the telephone pole that is up with nothing attached to it would be great for a loop for field day when I do 1 Echo.

OK,

I have done thing many times since I got my ticket in 1975.

Like two dipoles at right angles, say one for 80 and one for 40
connected to a single coax.

Of course it works and works great being the giant wide impedance's one
loads one is ignored depending on what freq being used.

BUT has anyone tried this, or would it even work?

I have mine like that but I made it also an inverted V as I don’t have the space around the house that is flat so I had to lower the ends of it. Not really a true V but it works.

73, WY6L

We all know a single dipole will not cover all of 80 meters with a good
match. The percentage of change is just far too much.

But what if you made two 80 meter dipoles. or more accurately described
a 80 meter one and a 75 meter one?

Say minimum swr at 3.6 MHz on one and 3.9 MHz on the other and both
antennas at right angles to each other.

Would this work? would one load better than the other because of the
better match? Are they far enough away from a good resonant match to work?

What happens at the middle of the band where the matches are close to
similar in SWR, but have oppisite reactances? One will be inductive
while the other capacative. hmmmm?

From: dean
Topic: 19204 Message: 19210

oops on the last post

My 40 and 80 fan dipole are at right angles to each other. The 75 meter one is N to S and the 40 meter is E to W. They are not totally an inverted V but the ends are very low. My radio is an FT-950 and the tuner in the radio tunes every band but 20 meters and 6 meters. For that I use the LDG 200 AT Pro. I can do DX quite well. If I can hear them I can work them. For 10,15, and 20 meters I mostly use my beam antenna which is about 2 ft. higher than my dipole. When I use my SB-200 it tunes great on 40 but not so well on 75. On 75 I get like a 2.5:1 . On 40 it’s a 1:1

in other words it works great at right angles.

73, WY6L

PS if anyone is close to Coarsegold, CA in the USA you are welcome to come over and try it out.

19216. Metal carport ideas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-15 18:55:10 UTC
From: kk4ej
Topic: 19216 Message: 19216

Recently added a metal carport, 18 x 20 ft.

Pondering ideas for HF antennas that could be installed easily and taken down to keep the spouse off the war path.

First thought was a 20ft "flagpole" that could hold the center on inverted V.

Then another was use the roof as the ground plane for a verticle.

Thoughts?

Randy

My first thought was the vertical. Make sure all the sections of the roof
are electrically bonded, and put the vertical in the center. Should work
like gangbusters.

Sounds like a great idea. I put a 40M vertical in the center of my work shop roof, with the car port overhang on one side it is a 55 x 70 ft metal roof. I did not work, as the heavily painted section do not have a good connections. It worked great when I added radials.

You can always use invible wire. # 30 or # 26 enameled wire. Or just the wire out of a small motor or transformer. Really hard to see it.

Well here goes! i have all my radio gear grounded to the outside via a 10ft copper braid to a 8ft copper rod.
My wife was trimming the shrubs outside the shack window while i was inside talking on 10 meters. She came in and asked me" what are you doing to the ants" to which i responded "what"? She told me that every time I keyed up the radio to talk the the ants around the ground rod would "dance"
I got her to come in and talk on the radio and sure enough when she talked the ants would seem to dance!
Whats going on?

Thanks

I just use a cage dipole (inverted vee). It's broad as a barn door. Even though the free program on smeter.net says it should have only 318 KHz BW and the sweet spot is around 3700 KHz, the VSWR is /just barely/ 2:1 at 4000 KHz. It's no big deal since I spend most of my time below 3900 KHz.

It's 4 wires, 125' OAL, and spreaders are 24"x24". I used 14ga 168-strand wire but could've used much smaller wire. Spreaders are Schedule 10 ½" dia PVC tubing. Since it's a cage, it needs no more supports than a dipole or inverted vee.

You're RICH!! You can sell your pest repeller--ants, mice, wasps, mosquitoes, and killer bees. Put it on Channel 14 CB where they let them run 500 Watt Diathermy's. Install it with the wire to ground as the antenna. Have your good looking lady salesman sprinkle test ants on it. I'll buy one.

This sort of problem is almost never the result of a virus or anything else the alleged sender has any control over.

The problem is that Yahoo does not use any technology to ascertain whether or not an email message is actually from the sender.

Armed only with James Wells email address (kdoajz@something.net) and the address of the Yahoo ham-antennas group (ham-antennas@yahoogroups.com), I can set up an SMTP server on any computer connected to the internet and send an email to the group claiming to be from James. Yahoo will accept it and forward to the subscribers and post to the website.

The moderator will then put James on moderation even though James and his computer had nothing to do with the message.

This is how spammers work.

You've got an RF problem!

When I was a teenager in the 1960's, I used to take a dynamotor out of some war surplus electronic equipmemnt to gather worms for fishing. For those who don't know, a dynamotor is a small motor-generator set used to generate the HV for portable tube equipment. Usually artound 300V or so. I would run the dyanmotor from a 12V battery and connect the HV leads to a pair of steel wires that I would push into the wet ground.

Turn the apparatus on and the nightcrawlers would come streaming out of the ground to get away from the current!

I wouldn't say that the O.P. (Original Poster) has an RF problem, the ants DO!

The copper in the ground is to make connection to the earth, which is conductive, and is providing a current carrying return for the antenna. (May not be intentional but is happening.)

It's the same thing as in a lightning strike; there is a gradient across the ground from the point of contact to the "out there" where the charge is dissipated to. Cows and people have been zapped because they were standing on and bridging that current path.

The ants were being electrocuted by the means that they were bridging the surface from the higher potential to the lower... conducting some of the O.P.'s good RF signal through their little bodies.

Those poor little ants! Shouldn't be zapping them! Now you'll have to mount an massive relocation project. Have it funded by tax dollars. Hire attorneys to settle any of the ant's claims... Councelling for your wife's wounded sensibilities cause she saw it happen...

And what about the worms??? Don't let me get started on the worms... please.

With tongue firmly planted in cheek... ;-)

There is a rudimentary internet RFC (RFC 4408 I think) that describes a technique called Sender Policy Framework. It boils down to creating an entry in your DNS database that can be queried to determine what the IP addresses are of mail servers authorized to send mail on behalf of your domain.

For example, if you were to look up the SPF record for hourglass.com (my domain), you would find an entry that point to servers belonging to thoughtbus.net (our mail provider).

A common anti-spam technique is to check the source of incoming emails against the spf record for the domain the email claims to be from. If they don't agree, you can flag the email as probable spam.

I suspect Yahoo doesn't implement this because of the volume of mail it receives. It requires a DNS lookup for every incoming email.

I was until recently a lecturer of the wiring regulations here in the UK and trying to teach students in a built up area that when installing in rural areas that you must site Electrical Earth Rods so as to not cause injury/death to livestock could be quite interesting! Also actually measuring the resistance of the Earth using the 3 rod method. In all honesty nobody does it they just use an Earth Loop Impedance Tester to inject a current in the Live/Line-Earth loop.

But yes currents flowing in the general mass of Earth can be "interesting" I also worked on the railways and when rolling stock with regenerative braking was introduced it cause problems with foundation steelwork on building around Victoria Station in London, this required extra bonding/return current cables to be installed to reduce it. It was not helped being DC the electrolytic effects just added to the problems.

Sorry off down memory lane.

As Al pointed out, there is almost certainly nothing wrong with your email account. You won't find a virus, nor will changing passwords help. The Internet is set up to trust servers, and if someone sets up a server and sends out email pretending to be from you, the Internet will simply pass it along as if it actually came from you. The place where it should be caught is coming in to Yahoo, before it gets to the group. Checking the originating IP address would reveal that it is a spoof message (i.e., not really from you).

I have my own domain, and at one point, I was getting up to 7,000 emails a day in response to spam that "hackers" were sending out using my domain. Very annoying, and there was really nothing I could do about it.

Good luck.

I would. (Say that the original poster does have an RF problem, that is.)

> The copper in the ground is to make connection to the earth, which is
> conductive, and is providing a current carrying return for the antenna.
> (May not be intentional but is happening.)

Shouldn't be happening.

Unless his antenna is a ground-mounted tower, and this ground rod is
at the base of the tower, and the braid to the ground rod comes from
the antenna end of his coax.

But he said the braid came from his "gear", which I took to mean his
electronics inside the shack.

What's supposed to be happening is that the transmitter sends an RF
current into the coax, all of which comes back on the shield of the
coax. Nothing should come back any other way. There should be no RF
current from his gear to or from a ground rod.

If there is, it means his antenna starts at the transmitter terminals
and includes the feedline itself and the wire to the ground rod.
That's probably not what he thought his antenna was.

Though I must say it could be fun to see the ants dance. I'm
wondering what that looked like.

Andy

Correct Andy, that's why my comment about it not being intentional but happening.
The antenna system in question was never mentioned, but probably might need a balun at the anteenna end, or more careful routing away from the radiator.

However, since OP doesn't seem to be experiencing any "hot mic" problems, the the ants are the ones who are feeling the pain... ;-)

19248. Re: CCD Antennas?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-16 21:20:11 UTC
From: Ben Franklin
Topic: 18238 Message: 19248

For what it is worth, I recently built an experimental 20 meter monoband CCD (Controlled Current Distribution) antenna. It works well and slightly outperforms my Buckmaster 4-Band OCF dipole.
This CCD antenna is specifically built to be stealthy and ultra lightweight. It is fabricated with 26 AWG stranded copper clad steel with black polyethylene insulation. The wire segments are directly soldered to the ceramic capacitors (axial leads), which are protected and concealed by black 4:1 dual-wall heat shrink tubing. The radials are very stealthy with only a slight bulge (3/16") at each of the capacitors. This antenna is very light and will not be able to handle any ice loading or high winds.
Each radial consists of eleven 31 5/16" segments (measured center to center between capacitors), 12 miniature 100pf 200 volt 5% ceramic capacitors and two 32" end segments, for a total of thirteen segments per radial. The two end segments are cut longer to allow for small loops for attachment to the balun and insulator. The antenna is fed into a LDG 4:1 200 watt voltage balun with low loss RG8 coax. I have run 100 watts SSB and 40 watts digital mode for long duty cycles with no failure of capacitors. SWR is nearly perfect at 1.0:1 from 14.1 mhz (but varies somewhat with height). Cost of materials was less than $60.

Noise levels with the CCD antenna are typically 10 dbm lower in comparison with the OCF dipole. After adjusting for noise levels, the CCD typically shows about 2 dbm greater gain than the OCF. My Flex 5000A calculates the true RMS power in dBm of the current signal (signal plus noise) within the passband, as measured at the selected antenna port.

If you build your own, please be advised that insulation and wire gauge both have a material effect on segment length due to reactance and velocity factors. Also, I would consider using capacitors with 1% tolerance in order to assure greater tuning accuracy. You must have an antenna analyzer to build one of these -- I used a Palstar ZM-30.

In testing the antenna I have observed some interesting results. First, it can be erected less than a foot off the ground as a flat dipole and maintain an SWR of 1.0: 1 across the entire band. Of course, in this configuration, the take-off angle is presumably very steep, but nevertheless I have worked Europe and the West Coast from my QTH in Maine with this ground level setup. This configuration is especially useful for anyone who needs a very stealthy antenna, however, the transmitted signal as reported by my contacts is typically down 9 top 12 db when compared directly with my OCF antenna (35 feet/inverted "V").
However, when the CCD is configured as an inverted "V" at 35 feet, I have noticed that many of my digital DX contacts are reporting RSQ 599 while their signals might be RSQ 448 or worse. This suggests that the CCD antenna has a nice low take-off angle and overall it outperforms my OCF dipole on 20 meters in this configuration. Finally, I have worked from New Zealand to Ecuador to Dubai with the CCD antenna and 100 watts SSB with good signal reports.

I am sufficiently encouraged by the results that I am now in the process of building a stealthy 20/40 dual band CCD. I am limited to simple wire antennas at my QTH -- towers and multi-element beams are not feasible, hence the interest in CCD technolgy.

Finally, if you are interested in CCD antennas, but don't need a stealthy antenna, you may want to consider purchasing a commercial product from CCDantennas.com The company also has information for builders and the owners are very helpful. I have no connection with the company.

What are these "radials"?

I'm guessing you are referring to each of the segments between capacitors that make up the antenna. Not exactly what most people mean by "radials".

I take it your description refers to a home-built version. If I remember right, pictures of the commercial version show bare wire used throughout.

If it were up to me I would design a pair of inverted L verticals spaced 1/4 wavelength apart. You could use a couple of trees to support the horizontal parts of the flat top of the L's at 40'. With a phasing network, either homebrew or bought from Comtek, you could have a nice 75 meter antenna with a good low angle of radiation and 3 DB of gain. BTW don't forget a good ground system. It's a great performer if you have the room for it.

I've also seen articles where folks set up a 2 element wire beams but inserting reactance into the elements to change the beam direction is do-able. But at low heights the 2 element vertical array should out perform it.

I agree Andy. Years ago our TV mast pole was stuck in the ground and held by a bracket to the eve. It shocked me. . My VOM measured about 70 volts AC from the pole to earth. The pole was NOT grounded. Also if the ants are jumping that shows a leakage current from equipment to ground. May be RF but sure hope it's not 60 or 120 Hz AC.

Andy -- Yes, the term is confusing and poorly chosen. I should have used the term elements, meaning the two elements that make up a conventional dipole. Each element has 12 capacitors and thirteen segments. The commercial product is not stealthy, consquently, I endeavored to fabricate a my own with low visibility insulated wire and cloaked capacitors.

I know you want to build one, but in all honesty nothing makes a better scanner antenna then a discone. That said it’s a hard build (for me at least), MFJ makes a good discone at a good price.

One trap per leg?? or 2 traps in ONE housing??
That is what is used in many 3 band designs (beam or vertical)
And so I would guess that then you can maybe use info from a different 3
band beam ...

19260. Yaesu FT-920 + goodies for sale

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-17 14:00:29 UTC
From: oceanbiz01
Topic: 19260 Message: 19260

Good Day to All.

While it pains me to do so, I am downsizing my shack and the FT-920 is part of the downsizing.
This 920 is in immaculate physical condition. I sent it to Yaesu to have the ATU repaired and Yaesu did the repair and in their repair report they mentioned that the FT-920 meets all Yaesu Specs. They went through a complete alignment apparently, following ATU repair. I have the documents from Yaesu to prove it.

Included:
FT-920
MARS/CAP 60 Meter Mod installed
Installed CW Filter, SSB Filter, AM Filter, FM Board and TCXO.
Original MH-31B8 Hand Mic still in it's box
Original Oscillator in separate box that was replaced with the TCXO
Spare red and green buttons for the RX and TX buttons. (I replaced one but had bought spares) .
Original Manual and DC power cord
As a bonus:
Donner Digital Systems interface for RTTY, PSK, SSTV etc. New unused and has the correct Mini DIN plug for FT-897D and FT-817ND. But also included in the correct large DIN plug for the DATA jack on the 920. Also included is a mating female connector for the MINI-DIN so that an adapter cable can be made to go from the Donner connector to the FT-920 .
All documentation will be included.

I worked a heck of a lot of DX with this radio from 160 through 6 meters. I just now turned it on and connected it to my vertical antenna just to make sure that it is humming right along and it sounds great. Transmits just as good.

Asking $950 free UPS Ground shipping to anywhere in the lower 48 states. Any place outside of the lower 48 will cost extra. I will like payment by Paypal . Paypal is preferred sent as a gift to avoid my being charged the Paypal 3% fee.

Also for sale:
TE Systems 0510G 6 meter brick amplifier with DC power Cord and manual $350.00 + shipping cost

MFJ-989C Versa Tuner 3 KW Roller Inductor type with manual. $250 + shipping cost

MFJ-1279 Digital Interface $50 + shipping

MFJ-1263 Microphone Switch $50 + shipping

Interested parties should email me directly at dan-schaaf@...

Thanks for your consideration

One trap per leg?? or 2 traps in ONE housing??
That is what is used in many 3 band designs (beam or vertical)
And so I would guess that then you can maybe use info from a different 3
band beam ...

Date: 2011-08-17 14:23:34 UTC
From: Dan Schaaf
Topic: 19260 Message: 19264

Hi Dale

When I sent it to Yaesu, they confiscated the original box and returned the 920 in a new box with poured foam packing. That box and packing is in excellent condition.

I smoke but not in the shack.

And all radios are covered when not in use.

Best Regards
Dan Schaaf

Hi Dan
I just sold my Drake C-line today,waiting for the pmo to arrive. I saw your ad for the 920,one of my favorite rigs,had one for several years before I got into the boat anchors...anyway Iam in Cape Coral and would pick up the 920 if I bought it.I can assume its never been around smoke? Do you still have the shipping boxs?
thanks
dale wt4t

Subject: [ham-antennas] Yaesu FT-920 + goodies for sale

Good Day to All.

While it pains me to do so, I am downsizing my shack and the FT-920 is part of the downsizing.
This 920 is in immaculate physical condition. I sent it to Yaesu to have the ATU repaired and Yaesu did the repair and in their repair report they mentioned that the FT-920 meets all Yaesu Specs. They went through a complete alignment apparently, following ATU repair. I have the documents from Yaesu to prove it.

Included:
FT-920
MARS/CAP 60 Meter Mod installed
Installed CW Filter, SSB Filter, AM Filter, FM Board and TCXO.
Original MH-31B8 Hand Mic still in it's box
Original Oscillator in separate box that was replaced with the TCXO
Spare red and green buttons for the RX and TX buttons. (I replaced one but had bought spares) .
Original Manual and DC power cord
As a bonus:
Donner Digital Systems interface for RTTY, PSK, SSTV etc. New unused and has the correct Mini DIN plug for FT-897D and FT-817ND. But also included in the correct large DIN plug for the DATA jack on the 920. Also included is a mating female connector for the MINI-DIN so that an adapter cable can be made to go from the Donner connector to the FT-920 .
All documentation will be included.

I worked a heck of a lot of DX with this radio from 160 through 6 meters. I just now turned it on and connected it to my vertical antenna just to make sure that it is humming right along and it sounds great. Transmits just as good.

Asking $950 free UPS Ground shipping to anywhere in the lower 48 states. Any place outside of the lower 48 will cost extra. I will like payment by Paypal . Paypal is preferred sent as a gift to avoid my being charged the Paypal 3% fee.

Also for sale:
TE Systems 0510G 6 meter brick amplifier with DC power Cord and manual $350.00 + shipping cost

MFJ-989C Versa Tuner 3 KW Roller Inductor type with manual. $250 + shipping cost

MFJ-1279 Digital Interface $50 + shipping

MFJ-1263 Microphone Switch $50 + shipping

Interested parties should email me directly at dan-schaaf@...

Thanks for your consideration

> AC from the pole to earth.

That one sounds like the kind of problem you get when some equipment
has a pair of 0.01 uF capacitors, one from each leg of the AC line to
chassis, in the days before grounded 3-prong power plugs. The caps
were supposedly there to bypass any RF noise from coming in on the
power line. But it makes a nice AC voltage divider and puts the
chassis at 120V/2 AC.

Yes, some professional equipment was actually designed that way!

It's not enough to kill you (if you and your surroundings are dry!),
but it is enough to draw some pretty nasty looking sparks.

> Also if the ants are
> jumping that shows a leakage current from equipment to ground. May be RF but
> sure hope it's not 60 or 120 Hz AC.

Sounds like it is RF in that case, since the ants dance only when he
was transmitting.

Andy

19266. Can rfi damage components?

> Besides being annoying, can rfi damage the components that it's interfering with?

Given the right circumstances, I'd say yes. Hypothetically.

For the RF itself to directly damage components, the amount of it needs to be significant with respect to the voltage tolerance of the device. For example, modern computer chips can't tolerate more than a couple of volts across their terminals, and if the circuit it is part of was designed with no RF immunity in mind (and sloppy electrical characteristics in general ... not likely these days if one wants to make a working computer, but you never know), then the RF *might* induce enough voltage across parts of the chip to zap it.

Some components are more delicate than others. Some MOSFETs are very hi-Z devices and are more easily damaged by static and stray voltages.

How much voltage you get depends on how close it is to the offending RF field and how much power is involved.

RFI could cause damage in other ways.

RFI into an audio system makes annoying, loud noises. With a powerful enough audio amp, it might blow out a speaker, or some transistors if not protected.

RFI into a computer might make it malfunction and erase data on the drive. But when computers crash or freeze, they don't usually take the drive down with them.

I suppose RFI into a susceptible thermostat might cause it to overheat your home.

I am not aware of cases where RFI damaged something. I am just saying that there is that potential.

Andy

19268. AW: [ham-antennas] Can rfi damage components?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-17 17:09:46 UTC
From: Siegfried Jackstien
Topic: 19266 Message: 19268

It depends
I would say in most cases not ... but if you are close to a rock concert and your rfi is getting in the audio equipment maybe you could blow up the tweeters in heaven ...:-(...

Maybe other things can happen ... it depends on what causes the rfi and how much the electronic device is influenced
A ham-friend blew up the voltage regulator from the solar panels in his mobile home with abt 400w on shortwave and a mobile antenna at the back end of the mobile home .. now guess what .. voltage was not controlled
In the sun the panels gave abt. 17-18 volts ... danger for all 12v equipment in the area!!
So .... it depends ...
Dg9bfc

19273. Antenna aging

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-17 20:36:29 UTC
From: k1eg
Topic: 19273 Message: 19273

Hi everyone,

I am working on a project for presentation at our annual ARES convention here in Kentucky and need some help finding information. As we all know antennas exposed to the weather derogate over time whether they are made from copper or aluminum. Many HAM's do not really think about this as part of their maintenance they should be doing.
What I am looking for is any information or studies that measured or shows how much antenna efficiency decreases over time from exposure to the weather. I have done extensive research online and in my engineering books and cannot find anything

Mike,

Here is an article that deals with coax cable degradation with weather conditions but can't find anything specific about antennas. I agree there should be something on the subject....and maybe some good ham out there will do a study and write an article that covers this!

I don't see the efficiency of the wire or porcelain or glass insulators changing, but my ~25 year
old 40 meter dipole made from 12 AWG copperweld almost rusted through completely in several places.
Anything plastic will change, mostly deteriorating from the elements and time. (and stretching)
The least noticeable thing effecting operation is the extremely slow deterioration of the polyethylene which is the center conductor insulation in the coax or on the windowing line.
Any physical hard bend of any coax and flexing from winds will result in physical crushing or other
damage to the center conductor insulation and possibly slow breaking of the inner conductor.
(strands if stranded) Frequently before 20 years has elapsed.

Coax commonly used by HAMs is covered with a vinyl jacket that was intended to be used indoors, coax
designed for exterior use is covered with polyethylene, the deterioration of the vinyl is effected
by the weather at the site, being mostly damaged by the rays of the sun. (also by the effects of
water and bacterial infections) Once the jacket of penetrated the water will corrode the shield
increasing losses quite a bit.
--
Ron KA4INM - Mistakes are often the stepping stones to utter failure.

My HF station went up in 2007 when I got my General ticket. The coax was bad when it went up but its still working great. I have new LMR 400 to go up in its place but I’m waiting on cooler weather and will be putting up a G-800DXA rotator.

I don't see the efficiency of the wire or porcelain or glass insulators changing, but my ~25 year
old 40 meter dipole made from 12 AWG copperweld almost rusted through completely in several places.
Anything plastic will change, mostly deteriorating from the elements and time. (and stretching)
The least noticeable thing effecting operation is the extremely slow deterioration of the polyethylene which is the center conductor insulation in the coax or on the windowing line.
Any physical hard bend of any coax and flexing from winds will result in physical crushing or other
damage to the center conductor insulation and possibly slow breaking of the inner conductor.
(strands if stranded) Frequently before 20 years has elapsed.

Coax commonly used by HAMs is covered with a vinyl jacket that was intended to be used indoors, coax
designed for exterior use is covered with polyethylene, the deterioration of the vinyl is effected
by the weather at the site, being mostly damaged by the rays of the sun. (also by the effects of

water and bacterial infections) Once the jacket of penetrated the water will corrode the shield
increasing losses quite a bit.

Hi Dean,

If I remember correctly back in the previous solar cycle as it was declining I believe there were studies showing this info to promote cleaning your antennas to improve your chance to work some rare DX. I have a gut feeling that the info was probably on AOL or Geocities websites which are long gone now. I found that after 1 year exposure to the weather cleaning my G5RV sure did help me pick out some rare DX. I suspect that DX'ers more so than rag chewers notice when their antennas start to decline. What got me going was Wireman advertising the "Silky" wire as having no more loss than a bare copper antenna exposed for 1 year to the elements.

Gary, The week prior to ARRL SS CW Contest, I refurbished an old
A3 tribander. While it is not an A4, it uses the same or similar
traps. I received a note from Cushcraft in response to a query I sent
them asking about the trap frequencies and a price list for
parts for the A3. I needed to replace an element segment, all the hose clamps
(they were not stainless), and all the trap end caps. I also had a high swr on 20m for the last few years. And recently,
10m swr went high. So I bought a new A3S and brought down the old
one. I marked all the element segments and traps (d1, d2, d3, etc...de1,
de2, de3, etc...r1, r2, r3, etc....) with a big felt-tip pen. I took all the element segments off the beam down to to the center
director, driven element and reflector element segments. To remove the old, rusted hose clamps, I simply twisted the screw
housings off with a pair of channel locks. It did no damage to the
element segments. I removed all the end caps from the traps. I cleaned/burnished all the element segment joints. I used an old B&W Model 600 Dip Oscillator to check resonance of all the traps. The 600 is a fine piece of equipment, but the
resolution of the dial for determing the real resonant frequency
is not that great. However, as long as the resonant frequency was
in the ballpark, I was happy. I used a couple of 2x4's to fix and maintain the position of the
traps as I checked them with the dip oscillator. Once I made a

couple of measurements, I put some masking tape down on the table
to mark the position of the 600. Essentially, it was simply a
matter of pointing the 600 coil end to end with the end of the
trap element segment away from the screw attachment end. As long
as the paired traps were in the same ballpark resonant frequency
range, I was happy. I found one trap that had no resonant point. I checked the
resistance of the trap (end trap element segment to end trap
element segment). Open. Next, I unscrewed the attachment screw. Using the procedure
described below, I removed the trap cover. The trap element
section consists of short piece of aluminum tubing, a length of
fiberglas insulator, and another piece of aluminum tubing. The
trap coil is wrapped on the insulator with the coil ends attached
to the respective tubing piece with a sheetmetal screw. Once the trap was free of the trap
cover, I scrapped away a bit
of the wire insulation of the coil and measured resistance between
it and each end of the trap element segment to see which end was
open. I removed the appropriate attachment screw, cleaned the
aluminum element segment at the screw hole, cleaned the trap wire
loop, reseated the screw, and checked the resistance. It was okay. Ultimately, I removed
all the covers of the traps to clean out any
insect infestation (found only one, but it wasn't bad at all)--I am
not sure how much stock to take in what I hear about insects
infesting antennas anymore. I have birds resting on my beam, wasps
flying around the tower all the time, and I only found a bit of an
infestation in one trap. Not bad! What I did find was that some of the trap spacers were
pretty eroded
by something. I am ordering some replacements to put in the next
time I work on the antenna. Once I received the parts I had ordered from Cushcraft, it was
a
snap putting the antenna back together. I set element lengths for
the CW portions of the bands. When it was raised to the 40' level
of my 70' tower and mounted on the side of the tower pointing NW,
I ran an SWR check and it was flat in the CW portion of the three
bands. Great! While lowering the antenna to the ground, we had let the reflector
end element segment stab the ground and bend. When I went to
remove it from the rest of the antenna, it broke away very easily.
I near the break, but not part of it, I found a 3/8" hole burned
in the the tubing. About four years ago, the house suffered what
I thought then was a near lightning strike. I had lost a bunch of
household equipment and ham equipment. I thought it was a near hit.
I lost 2 TNC's, a TR-7845, a 286 computer, a terminal used for
packetcluster work, garage door opener, a-c/heater controller,
television, and phone answering machine. Everything else (TS-930, rotator, wattmeter/SWR
meter--both of
which were connected to the antenna at the time of the strike--
stereo, VCR's, clock radios, kitchen appliances, washer/dryer,
etc.) was just fine. Lightning is strange stuff. ==========
Here's a message Cushcraft sent me about troubleshooting their antennas.
========== Adjusting the Antenna The suggested element lengths
will be correct for most

installations. The local environment may shift the point
of best VSWR. In this situation you may improve VSWR for
a specific frequency by making equal length adjustments on
each side of the center of the driven element. To adjust the highest frequency band adjust the tubing
length between the center of the element and the first
trap on the element. To adjust a center frequency band
adjust the spacing between the trap for that band and the
next higher frequency trap. To adjust the lowest frequency band adjust the length of
tubing beyond the lowest frequency trap. If you have a yagi adjust the driven element only. Leave
the reflector and director elements set to the suggested lengths. Troubles in the Antenna
If you fail to get a good VSWR on one band there are three
possible problems: One is that a trap is bad or mis-tuned.
Another is that nearby metal or other antennas have de-tuned
the antenna. The third is that a length of tubing section
has changed possibly due to loose clamps. First verify that all element lengths are correct and if you
have a yagi make sure that the element spacing is correct.
If the reflector and director spacings are swapped it will
have a serious effect on the impedance of the antenna.
Rotate the antenna and check VSWR at different azimuth
headings. Any variation in the VSWR is an indication that
nearby guy wires or other antennas are having an effect on
the tuning of the antenna. A trap is a high Q parallel resonant circuit. If the next
lower frequency does not work then a coil may be open. Do
not try to take a trap apart since this will void the
warranty. The balance between inductance and capacitance is
critical and requires special equipment to assure proper
adjustment. Refer to the trap troubleshooting section for
checking individual traps. VSWR changes with weather Ice or heavy snow tat sticks to the elements and traps will
cause the resonant frequency to shift lower since the
radiator will appear to be fatter. If you antenna is close
to the ground the effect of more conductive soil during wet
weather will shift the resonant frequency lower due to
capacitive loading. Any cracked or torn plastic caps will
allow moisture to ingress thus affecting the resonant
frequency of the traps. Putting any type of a sealant on the
butt end of the traps will likely de-tune them and create
voltage breakdown problems since the outer end of a trap is a
high voltage point. VSWR Changes with Power If VSWR varies with power level on one or more bands the
problem may be in the VSWR bridge (or harmonic content of
your PA). There can be a non-linear variation of diode action
at different power settings. This is common with inexpensive
bridges. It is possible to overload a diode in the forward
power mode. The diode is now on a different slope of the curve
in relation to the reflected power diode which is not overloaded.
The end result is that your VSWR will apparently increase when

you go from low to high power. Example: 1.1:1 at 50 watts,
1.4:1 at 800 watts. Observe VSWR as you slowly increase power.
If VSWR slowly increases you may be overloading your bridge.
If you see a large jump in VSWR at a specific power level, not
related to a slow increase in power, you have voltage breakdown troubles with your antenna
system. Causes: Poor or intermittent
connection in coax or connection in a trap. High voltage
breakdown in a trap can be detected by sniffing the end cap to
determine if it has burned. VSWR too high on one or more bands
Mistake in assembly or a defective trap. See trap troubleshooting.
Look for a trap in backwards. Look into tubing at each end of the
trap. The end where the self-tapping screw threads are visible is
the end that should be closest to the boom. Trap Troubleshooting The traps are a very
robust unit that should not require any
attention. Amateur power levels should not be capable of damaging
the coils or causing arcing under peak power conditions. Therefore
trap problems will usually be traced to mechanical faults that are
easily corrected. The first step you should take when you suspect a problem is to
locate the antenna so that you can work on it easily. For safety's
sake it is a good idea to have both your feet on the ground. (the
traps should be marked before removal so that proper reassembly is
assured). Check each trap to insure that the cover is tightly secured. The
cover is the 1-5/8" tubing between the two large black end caps.
Any movement of this cover will cause an intermittent VSWR
condition on the antenna. You may easily test for a loose cover
while the antenna is still assembled. Grasp the cover in one hand
and the trap tubing in the other hand, apply a moderate amount of
pressure first in a clockwise and then a counterclockwise direction
about the axis of the element. If the cover slips even a small
amount it will require tightening. Remove the black cap from the
trap on the side towards the boom of the antenna. A hex head screw
will then be visible underneath. Tighten the screw with an
appropriate screwdriver or nut driver. Be careful not to apply so
much force as to strip out the sheetmetal screw. If the hole is
already stripped, or gets stripped accidentally, it is an easy
matter to be fixed by substituting a #10 3/8" or 1/2" self-tapping
screw into the enlarged hole. If all your traps pass the mechanical test and seem to be
installed properly, then a frequency check is in order. (The
traps should be marked before removal so that proper reassembly
is assured.) Place a trap on an insulated surface (such as a large cardboard
box) and couple a dip oscillator to it as shown. Make sure to
couple it to the end of the trap that was closest to the boom,
the end of the trap that was self-tapping treads visible inside
the tubing. Insert the tip of the dip oscillator coil slightly
into the tubing. When a dip is found pull the oscillator coil
out of the end of the trap slightly and re-dip the oscillator.
Continue to pull the dip oscillator coil out of the tubing and
re-dip until you have the smallest perceptible dip. It should
be noted that the dip meter frequency is lower than the
operational frequency of the trap. This is caused because the

trap will load the dip oscillator and lower its frequency. TRAP Oper Dip Osc Freq. Freq. TA
28.60 27.50
TB 21.50 20.39
TC 21.30 20.20
TD 28.00 27.00
TE 28.80 27.60
TL 24.90 24.15
TM 18.11 17.29
TN 21.30 20.20
TK 14.18 12.62 You should use the listed oscillator frequencies as a guide.
Temperature and humidity can have a +/- 100KHz effect on traps.
If the readings are within 200KHz of the listed amounts, do not
worry, the effect upon the assembled antenna will be minimal.
Shorted turns or other serious defects will cause wide shifts
from the norm. One or two megahertz is a definite indication
of a defective trap. If you find such a trap, do not attempt
to repair it yourself as this would void the warranty. All
coils are sealed and are difficult to repair properly. When
all traps are checked and corrected, reinstall them in the
proper order and your antenna is now ready for action. ==========
Here's a note a friend forwarded to me on how to work on the traps.

Sender: owner-cq-contest@...
Reply-to: CARLO2@... (Brian McGinness)
To: To: CQ-CONTEST@... Hi Ward. I could not reply directly because you did not give
your email address at the end. Some of us out here are still
on ancient mainframe e-mail systems! Hi. Your traps can be both tested and repaired quite
easily. To
test them you need a functioning grid-dip-meter or an MFJ
antenna analyzer with their grid-dip antenna for it. I have found the best way to couple to
the trap using the MFJ
is to slide the stubby antenna inside the inner trap tube, and
hold the whole thing up in the air on the end of the analyzer
so other objects do not influence it. Then you will see a
SLIGHT dip in the SWR at the resonant freq of the trap. It is
a very slight, hardly noticeable dip depending on how well you
are coupled. I suspect the dip is easier to see using a real
grid-dip meter. I don't have the exact trap frequencies with me, but the inner
10 meter trap should dip around 27.5 (plus or minus a few
hundred kc, it is not critical) and the outer 15 meter trap
should have a dip around 20.3 or so, if I remember correctly. No doubt all your traps are
full of bug stuff. Actually, in
spite of what Cushcraft says, they are easy to open and repair.
To open them, remove the end caps. Then loosen the single
cover screw, and slide the center tube up inside the trap as
far as it will go (away from the screw end). Then stick the
HANDLE of a rubber mallet or hammer into the trap past where

the screw went, and tap the trap down against the hammer to
use the handle to drive the end insulator out of the side that
is not screwed in. That will generate enough force to slip the
insulator past the points in the cover that are center punched
to hold the trap together. Do no try to pry the insulators out,
it will not work, they have to be driven out with force. To
reassemble, tap the insulator back into the trap cover with a
rubber mallet. While inside the trap, check for corrosion at the screw terminals
and the trap inductor, and clean any debris and scorched areas. YOUR RESULTS MAY VARY!!!
Work carefully with them, and you can
fix them yourself, although it does take the proper touch. Good luck and 73,
Brian

Well to answer some questions that was raised. I have a Doublet that is 133+' and 65-75' above ground. I know some of you will say that that is enough antenna for anyone. However the situation that I have is that I would like to have something a little more quieter. I am a die hard believer that wire antennas is what the Ham Gods want us to use at all times (my opinion).

WY6L I thought about a loop but when I measured my yard I was not able to come up with a pattern that will give me the 529' so that I can work 80-10. The Inverted "V" that I will put up will be cut for 80m and since I am feeding it with 400 ohm ladder line and a balun that should make it all bands.

AB2ZY thank you for reminding me of that design. I had a senior moment there (HI HI).

For those that just read and wonder why I such a question well the issue is that I only have one feed point and that is my center support that I made out of plexi-glass. I designed it for a "V" or dipole so I could have either or. Now I want both.

Hi Harold,

Have you considered the linear loaded inverted V ? It will give you 160 through 10 meters and is very quiet.

Mike,
 There you go! You can start a cottage industry by advertising to clean antenna copper and aluminum.
 Sorry, but after 55 years as a ham, I have never ever heard of this. Coax, connections, etc sure, but wire and aluminum? Hmmmmm...
 I am just not sure that conductivity changes with age.

Hi Ron,

I do know from experience working DX in the last declining solar cycle
that after a year of my G5RV being up I could hear a difference in
received signals. I cleaned the copper and put it back up and there was
a noticeable difference in received signals.

19284. AW: [ham-antennas] Re: Inverted V

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-18 07:28:29 UTC
From: Siegfried Jackstien
Topic: 19198 Message: 19284

Hi Harold
Make a loop for 80 with a switch opposite of the feedingpoint
Now you can open the loop for 160 and use it as "bent" dipole ...
A friend from me had the same problem
He turned his antenna around ... I will try to explain what I mean:
He had the feedingpoint at the house and the other side was in the backyard
... as ladderline has low loss it is no problem to have a longer run of it
Now the feedingpoint is on a wooden pole (or tree) in the garden and the
loop´s other side is going close to his house ...
And that other side he routed to a window-frame where he can easy reach it
Now the loop can be closed or opened easy by hand
(exactly he has a short ladderline piece to the frame and 2 banana-plugs
g)
But sure similar could be dome remote with a vacuum relay
the thing is: closing or opening of that bridge not only effects working on
80 or 160 ... it also changes patterns on the higher bands ... so sometimes
on 15 or 20 a signal is better when loop closed or when loop open
you have to make a chart for the tuning in both cases for faster setting
...
But most of the time you will let the bridge closed as the antenna is more
quiet when it is in loop configuration ...
It is no problem if the loop is not a delta or square ... major part is MUCH
WIRE AND HIGH UP ...
Greetz

Hi Dale

I am getting several inquiries on teh FT-920. You were the first to reply to my sale. So, you have first refusal.
If you are interested, please let me know.
If you are NOT interested, also please let me know so that I can proceed with discussions with the other inquiries.
Yes, I know that you are 27 miles south of me and we can reduce the price for local pickup. You are certainly welcome to have a look at it and put it on the air here in my shack to confirm it's operation.
But PLEASE let me know one way or the other so that I do not keep these other inquiries hanging and waiting.

Best Regards

Hi Dan
I just sold my Drake C-line today,waiting for the pmo to arrive. I saw your ad for the 920,one of my favorite rigs,had one for several years before I got into the boat anchors...anyway Iam in Cape Coral and would pick up the 920 if I bought it.I can assume its never been around smoke? Do you still have the shipping boxs?
thanks
dale wt4t

Subject: [ham-antennas] Yaesu FT-920 + goodies for sale

Good Day to All.

While it pains me to do so, I am downsizing my shack and the FT-920 is part of the downsizing.
This 920 is in immaculate physical condition. I sent it to Yaesu to have the ATU repaired and Yaesu did the repair and in their repair report they mentioned that the FT-920 meets

all Yaesu Specs. They went through a complete alignment apparently, following ATU repair. I have the documents from Yaesu to prove it.

Included:
FT-920
MARS/CAP 60 Meter Mod installed
Installed CW Filter, SSB Filter, AM Filter, FM Board and TCXO.
Original MH-31B8 Hand Mic still in it's box
Original Oscillator in separate box that was replaced with the TCXO
Spare red and green buttons for the RX and TX buttons. (I replaced one but had bought spares) .
Original Manual and DC power cord
As a bonus:
Donner Digital Systems interface for RTTY, PSK, SSTV etc. New unused and has the correct Mini DIN plug for FT-897D and FT-817ND. But also included in the correct large DIN plug for the DATA jack on the 920. Also included is a mating female connector for the MINI-DIN so that an adapter cable can be made to go from the Donner connector to the FT-920 .
All documentation will be included.

I worked a heck of a lot of DX with this radio from 160 through 6 meters. I just now turned it on and connected it to my vertical antenna just to make sure that it is humming right along and it sounds great. Transmits just as good.

Asking $950 free UPS Ground shipping to anywhere in the lower 48 states. Any place outside of the lower 48 will cost extra. I will like payment by Paypal . Paypal is preferred sent as a gift to avoid my being charged the Paypal 3% fee.

Also for sale:
TE Systems 0510G 6 meter brick amplifier with DC power Cord and manual $350.00 + shipping cost

MFJ-989C Versa Tuner 3 KW Roller Inductor type with manual. $250 + shipping cost

MFJ-1279 Digital Interface $50 + shipping

MFJ-1263 Microphone Switch $50 + shipping

Interested parties should email me directly at dan-schaaf@...

Thanks for your consideration

Dan K3ZXL

Subject: Re: [ham-antennas] Can rfi damage components?

> Besides being annoying, can rfi damage the components that it's interfering with?

Given the right circumstances, I'd say yes. Hypothetically.

For the RF itself to directly damage components, the amount of it
needs to be significant with respect to the voltage tolerance of the
device. For example, modern computer chips can't tolerate more than a
couple of volts across their terminals, and if the circuit it is part
of was designed with no RF immunity in mind (and sloppy electrical
characteristics in general ... not likely these days if one wants to
make a working computer, but you never know), then the RF *might*
induce enough voltage across parts of the chip to zap it.

Some components are more delicate than others. Some MOSFETs are very
hi-Z devices and are more easily damaged by static and stray voltages.

How much voltage you get depends on how close it is to the offending
RF field and how much power is involved.

RFI could cause damage in other ways.

RFI into an audio system makes annoying, loud noises. With a powerful
enough audio amp, it might blow out a speaker, or some transistors if
not protected.

RFI into a computer might make it malfunction and erase data on the
drive. But when computers crash or freeze, they don't usually take
the drive down with them.

I suppose RFI into a susceptible thermostat might cause it to overheat
your home.

I am not aware of cases where RFI damaged something. I am just saying
that there is that potential.

Andy

Hi Mike...

I don't think signal degradation for amateur radio antennas is a big problem for either aluminum or copper antennas; the feed line, ground, and the various connections are different matters, however. Another "problem" will be the lack of quality information as to either reception or transmitted signaldegradation; most will probably be anecdotal and empirical.

Might check with the commercial broadcasters; FCC might have them do periodical checks.

Hi everyone,

I am working on a project for presentation at our annual ARES convention here in Kentucky and need some help finding information. As we all know antennas exposed to the weather derogate over time whether they are made from copper or aluminum. Many HAM's do not really think about this as part of their maintenance they should be doing.
What I am looking for is any information or studies that measured or shows how much antenna efficiency decreases over time from exposure to the weather. I have done extensive research online and in my engineering books and cannot find anything

Ok... one other thought.

Worst environment I can think of for any HF antenna would be on a ship out at sea. Find a navy radioman and ask what the "manual" has to say on the subject.

Hi Dean,

If I remember correctly back in the previous solar cycle as it was declining I believe there were studies showing this info to promote cleaning your antennas to improve your chance to work some rare DX. I have a gut feeling that the info was probably on AOL or Geocities websites which are long gone now. I found that after 1 year exposure to the weather cleaning my G5RV sure did help me pick out some rare DX. I suspect that DX'ers more so than rag chewers notice when their antennas start to decline. What got me going was Wireman advertising the "Silky" wire as having no more loss than a bare copper antenna exposed for 1 year to the elements.

Rattler, yours is not a new question. There are probably a ton of old threads discussing it.

The main reason that it is not the best option, except if you're planning to run through low, thick, bushes, Jeep style, is that as the whip becomes less and less of a wavelength, actually quarterwave length, its radiation resistance drops... drastically! Leaving only the actual resistance, copper and ground losses, to take over, turning most of your RF into heat. The same line of reasoning applies to how effective shortened, or very few, radials are under a vertical antenna.

As the antenna becomes a very small part of a wavelength, the main current is reactive - capacitive. Circulating current which doesn't radiate, only warming up the matching network and connecting leads.

I'm not sure, but I seem to remember typical efficiencies in the order of a percent or two are to be expected of a naked steel whip at eighty meters.

I'd love to use one myself, if it'd work.

Stan

Hi James,

Thank you for that answer. That is an excellant idea. I have contacted Press Jones, N8UG of Wireman and he indicates that the velocity factor of the wire changes with oxidation but I believe there is more to it than that alone.

Would it be practical to put in a 102" SS whip on my vehicle with a tuner. Ham sticks are nice but it would be nice to just put it on any band and tune with my LDG AT-200Pro autotuner. Not sure if its practical or not.

Hi all

I am trying to get into PIC circuits and I wondered if anybody had any advice as to circuits/programmers best suited to beginner on limited funds. I have looked on ebay and have downloaded a couple of books but advice is welcome. I do not plan to go into production or anything but I want to try and dip my toes into this as lots of things seem to be going this way. PIC a star/ PIC a tune etc.

cheers

Also there is skin effect. The higher you go in frequency, the more the current tends to confine itself to a narrow layer (skin depth) on the surface of the wires or elements. As the surface oxidizes, its AC resistance goes up. DC/low frequency resistance stays about the same.

In the oxidized area, but wouldn't the rf current just move down a few microns into the wire and flow through fresh copper avoiding the old
"oxidized surface" altogether?

Hi Andy,

You are dead on about the AC resistance going up and the received signals will be attenuated because of it. This is why I am looking for studies that may have been done. If I cannot find any then I will have to consider doing a year long test to see what the numbers may be.

From: goldtr8@charter.net
Topic: 19290 Message: 19299

I did this for awhile with my jeep and also used hamsticks.

With the whip it will work good on 10m, you will be able to tune it as low as 20m. But as others stated you will be inefficient as you get further away from a true 1/4 wave.

I ultimately gave up and got a Scorption Screwdriver as I wanted to be heard.

Below 40m the hamsticks were not very effective due to the small coils sizes.

Good luck and have fun.

Tune the 75 neter Hamstick to the area of the band you will use the most. Then use the tuner to keep the radio happy if you go up or down the band.

Now the Hamstick is not the most efficient 75 meter mobile antenna. But I had one that I used with the big 3 magnet mount on top of my pickup truck roof. It worked ok for what I wanted it to do, I was not looking to work DX or the west coast on it.

My later Father made a mobile antenna up for his van. It consisted of about 6 feet of aluminum tubing with a 102 inch stainless steel whip attached to that. He ran an Icom AH2 tuner right close to the feed point of the antenna. He did ok on 40 and up while mobile. Not sure how well it worked on 75 though.

Hi Jon:

I played with the microchip PICS for a while, learning as I went. I used the MPLab which worked well and a kit programmer.

My goal was for a model railroad project as well as some ideas for HAM use. There is a learning curve, assembly language was new to me. Start small, do simple projects first. Good old LED blinker is normally the first program to learn with.

Overall, once you get the chip setup the rest is just logic.

They are incredible at what can be done with them for a few dollars!

The PICKIT 2 @ about $35 USD is, IMO, a much better option than purchasing a demo board that may only be capable of programming one series of PIC devices. At best, it's maybe a few bucks more than one of the Velleman demo kits.

I prototype my projects with one of those ubiquitous breadboards you can buy at any hamfest and a 5V wall wart PS that came out of the junk drawer. The PICKIT 2 and like devices can provide power if you need it and are capable of facilitating in circuit debugging, which you will want once you get much beyond turning an LED on and off.

It isn't as easy as that. If the oxidized layer was a nice thin layer of insulator, surrounding unaffected metal, then it would do as you say; but it builds up as a higher resistive material, which supports part of the current (depending on the skin depth w.r.t. the thickness of oxidizing material). Yes the higher resistance pushes some of the current down lower into the wire, but it can't avoid flowing through the crappy part near the surface.

It may be a complicated function of frequency, metal, oxidation, year into the solar cycle, etc. So I don't know how much the effect actually measures at typical ham frequencies.

I do not know where I heard it but I remember way back being told either enamelled copper wire or tinned copper wire for wire antennas, probably old wife's tale but I have gone the enamelled route, oh and another no no is that I have not used hard drawn wire so the tuner has to cover a bit of stretch but hey it works and that is the main thing.

And it may not be all that complicated either. I would be interested in reading any reports on the issue. Also, I would be quite surprised if anyone has measured any differences in received signal strength between fresh and oxidized wire,

Any studies would have to be done in a lab as there are far to many variables in a typical ham station to make any meaningful measurements attempting to correlate signal strength versus oxidation on the antenna wire.

That seems to indicate an antenna made with stainless steel wire may be better than one made of
copper, it would never develop that problem. I think 29 MHz is a bit low to be so severely effected
by the skin effect.
If a layer of corrosion like this will effect "weak signal reception" so much think what an improvement will be realized by buying a "modern state of the art" radio.

Once you get into real projects, you will want the ability to reprogram and debug the device in the target circuit.

I use a standard 0.1"/2.54mm spacing 6 pin header in my projects that mates with the PICKIT. If I want to make a software change, I just have to pop the cover, plug the PICKIT into the header and bring up the project on my computer.

That would be something like a Texas bug catcher, top loaded, 3-4" loading coil (small top hat)
with a tiny coil at the feed point. No question. The uglier it is the better it will work!

Coax with a polyethylene jacket and solid polyethylene inner conductor insulation.

If you need a way smaller coax (say to wind a stepup or stepdonw in the
input side of a pa) the there are many smaller coax available
If you do not make tooo small winding nearly any coax can be coiled up

19318. Fwd: [ham-antennas] Antenna aging

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-19 20:48:21 UTC
From: DVC3565@aol.com
Topic: 19318 Message: 19318

Ron: There IS "skin effect," even at 29 Mhz. That's why even tube amplifiers with silver plated tank
circuits almost ALWAYS need a tuned input circuit on 10 Meter's and above. (I know, as I had
some "problems" with my home brew linear and HF damage, UNTIL I finally redesigned it and
put a tuned input on 10 meters.) And today's solid state linear's don't last long on 10 M, if things
are not SWR/output stable on 10. My 25 cents after 30 + years of building.
Also that new modern state of the art radio can have a signal floor of 1 micro volt for 20 db gain,
but IF there isn't any signal to amplify..it's all noise. The old timer's know what QQQ means.
(It's an "old" Q signal meaning "clean your antenna"-for the younger crowd.)
Something a kin to the "wouff hong."
73 es Gud DX to U
Dave-KJ4PF

That seems to indicate an antenna made with stainless steel wire may be better than one made of
copper, it would never develop that problem. I think 29 MHz is a bit low to be so severely effected
by the skin effect.
If a layer of corrosion like this will effect "weak signal reception" so much think what an
improvement will be realized by buying a "modern state of the art" radio.

Topic: 19320 Message: 19320

With all the talk about 43' verticals, I'm jumping in. I have a nice branch that I can hang some 18ga wire from and plan to use a SGC 237 tuner at the base. Has anyone tried this? I'm somewhat limited for space for radials. I know the more the merrier, but what is a reasonable minimum number? Will this present a problem to the tuner?

Should work great. The old WWII Command rigs had a short antenna the transmitter matched to. But the shorter the random wire the worse the radiation is. The Command rigs just ran about 10 watts talking plane to plane.

Topic: 19320 Message: 19324

Hi Lou,

This is from the ARRL antenna book:

Practical Suggestions For Vertical Ground Systems

At least 16 radials should be used if at all possible.
Experimental measurements and calculations show that with
this number, the loss resistance decreases the antenna efficiency
by 30% to 50% for a 0.25 wavelength vertical, depending on
soil characteristics. In general, a large number of radials (even
though some or all of them must be short) is preferable to a
few long radials for a vertical antenna mounted on the ground.
The conductor size is relatively unimportant as mentioned
before: #12 to #22 copper wire is suitable.
a.. If you install only 16 radials they
need not be very long - 0.1 lambda is sufficient.
b.. If you have the wire, the space and the patience to lay
down 120 radials (optimal configuration), they should
be 0.4 lambda long. This radial system will gain about 3 dB
over the 16-radial case.
c.. If you install 36 radials that are 0.15 lambda long, you will
lose 1.5 dB compared to optimal configuration.
---

Sorry Dean, I'm not going to lower my antenna just to take a photo. A word picture will have to do. Each spreader (four on either side of the feedpoint) is 24"x24", made from four 12" pieces of 1/2" PVC, glued into a cross. My FD and home QTH antennas depart from there. The spreaders for the FD antenna have the tips of the tube slotted to allow the 7-strand 14ga hard drawn copper wire to squeeze in. A hacksaw or bandsaw works nicely. The spreaders for the home QTH have holes drilled thru the tips, and I pass 168-strand 14ga hard drawn PVC-covered copper wire through the holes. Black (UV resistant) cable ties hold the spreaders in place. In both antennas, there is a spreader around 5' from the ends and center. The remaining spreaders split the distance between them and the end/center spreaders.

The weight of 500' of wire adds up quickly. In retrospect, 16ga wire would've cut the weight without compromising strength. Still, they've been OK. I use split-bolt connectors to ensure a good mechanical & electrical connection. They can be found in your home improvement box store for not a lot of dough.

My OFCD is made with 1.5mm enamelled copper wire, it is the 100ft one, if I can make a few suggestions. First tin the wire ends that connect to the balun, waterproof the balun, and then waterproof the waterproofing. This is especially true here in the UK. lower antenna every year for maintenance. It is amazing the difference in SWR before and after. things deteriorate so gradually you do not notice.

Unless the balun is very mechanically well built mount it on something UV proof that will also have points to take strain of the antenna wire. I use plastic guttering, if gently heated with hot air gun it becomes pliable and then flatten between heavy books etc. just drill out and away you go.

Have fun and hope to catch you on the bands

Hi Ross,

Besides all of the other very good suggestions, very thin copper wire would break quite easily so I would use Copperweld or a similar type of wire for it's strength. One supplier has it as thin as 18 gauge (breaking point is 280 pounds). There is also a very thin 26 gauge stranded copper clad wire that's insulated that is very flexible & also is stronger than thin copper wire. The problem with thin copper wire is that it breaks easily so this is one solution that will help keep the antenna up & working longer. Here's one supplier for reference to see the available ;

Dean, that picture is showing two 1:1 baluns wired together to form a 4:1 Guanella current balun. The wire is not wrapped on PVC but it is 10MM ferrite rods wrapped with a couple of layers of Teflon pipe tape and a wrap of regular electrical tape at the ends to hold the Teflon in place while the magnet wire is wrapped. The dual windings are spaced .025 with monofilament fishing line then the assembly is has a light coat of quick drying epoxy to hold it in place. The completed balun was then tweaked to a center frequency of 10-MHz to give good coverage from 75M thru 10M. The next evolution of this type is a indoor balun on 1/2" or 13MM ferrite rods to feed my 450 ohm line and it is switchable between a 1:1 or a 4:1 balun setup. This can be seen at http://s1102.photobucket.com/albums/g453/KD0ZZ/

Rich , Kd0zz

My OFCD is made with 1.5mm enamelled copper wire, it is the 100ft one, if I can make a few suggestions. First tin the wire ends that connect to the balun, waterproof the balun, and then waterproof the waterproofing. This is especially true here in the UK. lower antenna every year for maintenance. It is amazing the difference in SWR before and after. things deteriorate so gradually you do not notice.

Unless the balun is very mechanically well built mount it on something UV proof that will also have points to take strain of the antenna wire. I use plastic guttering, if gently heated with hot air gun it becomes pliable and then flatten between heavy books etc. just drill out and away you go.

Have fun and hope to catch you on the bands

Jon

Subject: RE: [ham-antennas] Thickness of HF wire antenna's

Dean, that picture is showing two 1:1 baluns wired together to form a 4:1 Guanella current balun. The wire is not wrapped on PVC but it is 10MM ferrite rods wrapped with a couple of layers of Teflon pipe tape and a wrap of regular electrical tape at the ends to hold the Teflon in place while the magnet wire is wrapped. The dual windings are spaced .025 with monofilament fishing line then the assembly is has a light coat of quick drying epoxy to hold it in place. The completed balun was then tweaked to a center frequency of 10-MHz to give good coverage from 75M thru 10M. The next evolution of this type is a indoor balun on 1/2" or 13MM ferrite rods to feed my 450 ohm line and it is switchable between a 1:1 or a 4:1 balun setup. This can be seen at http://s1102.photobucket.com/albums/g453/KD0ZZ/

Rich , Kd0zz CONTINUING SEARCH FOR PERFECT ANTENNA

Subject: Re: [ham-antennas] Thickness of HF wire antenna's

What is the diameter of the pvc the copper wires are wrapped around. It looks very nice. I do not have a balun on my antennas but I do have an RF choke just below each antenna. About 6 to 8 turns of coax about 10" in diameter.

For weather proof balun protection I use a PVC box, 2x4x4 or 50mmx100x100
with a o-ring lid. The cost about $6 at a big box store. SS eye bolts to
stop rust and corrosion.

It's not cheaper, just "galvanized steel" as apposed to aluminum. The "galvanized steel" would
be better from a tensile strength aspect, (which is great for stealth and longer antennas) but every
4 or 5 years it would need to be replaced because of rust. (depending on the weather)

Just checked out price of 400m of 2.5mm Aluminium wire at electric fence website works out at £84 ($138) including taxes but not delivery. Cheaper option would be Aluminium MIG/MAG welding wire, my £8 for 1lb of 1.5mm enamelled copper wire doesn't seem so bad now!

I must admit I am tending to use a lot of cat 5e now days, not prohibitively expensive, and providing not under too much tension works well. Saying that I am only running 100W, I will hopefully finish my large loop 500ft approx but only 5ft high soon so see how that goes.

I have the in-shack 998 and it is fantastic. I managed to get a Beta software from the MFJ engineer so that I can run it on my PC and tune the tuner with mouse click and also select all of the different functions of the tuner and switch antennas all from the PC. And the software has bar graphs to show power out and SWR and reflected power. It also shows how much capacitance and/or inductance was needed to tune the antenna system. And you can click a button to save settings for any frequency. And you can click to bypass the tuner.
They never published or sold the software. I got lucky.

Yes the 998 with power down to 160m.

I was using it today as well with the NA qso party.

From: Larry Tooley
Topic: 19323 Message: 19350

Aluminum sounds great. It's cheap easy to bend and lightweight. I wounder if a dipole blowing in the wind would break?

I tried some MIG alum welding wire years ago but it did not seem to hold up
in the weather, it got brittle.

Rich

Sent: Saturday, August 20, 2011 4:25 PM
To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Cost of Aluminium wire

Just checked out price of 400m of 2.5mm Aluminium wire at electric fence website works out at £84 ($138) including taxes but not delivery. Cheaper option would be Aluminium MIG/MAG welding wire, my £8 for 1lb of 1.5mm enamelled copper wire doesn't seem so bad now!

I must admit I am tending to use a lot of cat 5e now days, not prohibitively
expensive, and providing not under too much tension works well. Saying that
I am only running 100W, I will hopefully finish my large loop 500ft approx but only 5ft high soon so see how that goes.

Subject: RE: [ham-antennas] Thickness of HF wire antenna's

Dean, that picture is showing two 1:1 baluns wired together to form a 4:1 Guanella current balun. The wire is not wrapped on PVC but it is 10MM ferrite rods wrapped with a couple of layers of Teflon pipe tape and a wrap of regular electrical tape at the ends to hold the Teflon in place while the magnet wire is wrapped. The dual windings are spaced .025 with monofilament fishing line then the assembly is has a light coat of quick drying epoxy to hold it in place. The completed balun was then tweaked to a center frequency of 10-MHz to give good coverage from 75M thru 10M. The next evolution of this type is a indoor balun on 1/2” or 13MM ferrite rods to feed my 450 ohm line and it is switchable between a 1:1 or a 4:1 balun setup. This can be seen at http://s1102.photobucket.com/albums/g453/KD0ZZ/

Rich , Kd0zz CONTINUING SEARCH FOR PERFECT ANTENNA

Subject: Re: [ham-antennas] Thickness of HF wire antenna's

What is the diameter of the pvc the copper wires are wrapped around. It looks very nice. I do not have a balun on my antennas but I do have an RF choke just below each antenna. About 6 to 8 turns of coax about 10” in diameter.

Subject: RE: AW: [ham-antennas] Thickness of HF wire antenna's

For weather proof balun protection I use a PVC box, 2x4x4 or 50mmx100x100 with a o-ring lid. The cost about $6 at a big box store. SS eye bolts to

stop rust and corrosion.
http://i1102.photobucket.com/albums/g453/KD0ZZ/NewBalun.jpg

Rich , Kd0zz

My OFCD is made with 1.5mm enamelled copper wire, it is the 100ft one, if I
can make a few suggestions. First tin the wire ends that connect to the
balun, waterproof the balun, and then waterproof the waterproofing. This is
especially true here in the UK. lower antenna every year for maintenance. It
is amazing the difference in SWR before and after. things deteriorate so
gradually you do not notice.

Unless the balun is very mechanically well built mount it on something UV
proof that will also have points to take strain of the antenna wire. I use
plastic guttering, if gently heated with hot air gun it becomes pliable and
then flatten between heavy books etc. just drill out and away you go.

Have fun and hope to catch you on the bands

Don't do it!!! as ex railwayman it is something I actually know about. signalling uses upto 600 volts DC/AC at various frequencies between rails, in electrified areas most times return current path so could have upto 2KA running through it. I suppose if you were in the middle of the Nullabor desert or similar you may be OK but otherwise Don't do it even in jest.

I had some friends who used jumper cables across tracks close to a RR crossing. It would drop the arms then when they took the cables off the arm would go back up after a short bit. Like a train coming and going. They got the idea from our Electronics teacher.

Subject: RE: AW: [ham-antennas] Thickness of HF wire antenna's

For weather proof balun protection I use a PVC box, 2x4x4 or 50mmx100x100

with a o-ring lid. The cost about $6 at a big box store. SS eye bolts to

stop rust and corrosion.

http://i1102.photobucket.com/albums/g453/KD0ZZ/NewBalun.jpg

Rich , Kd0zz

My OFCD is made with 1.5mm enamelled copper wire, it is the 100ft one, if

I

can make a few suggestions. First tin the wire ends that connect to the

balun, waterproof the balun, and then waterproof the waterproofing. This

is

especially true here in the UK. lower antenna every year for maintenance.

It

is amazing the difference in SWR before and after. things deteriorate so

gradually you do not notice.

Unless the balun is very mechanically well built mount it on something UV

proof that will also have points to take strain of the antenna wire. I use

plastic guttering, if gently heated with hot air gun it becomes pliable

and

then flatten between heavy books etc. just drill out and away you go.

Have fun and hope to catch you on the bands

19358. RE: [ham-antennas] Cost of Aluminum wire

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-21 14:58:29 UTC
From: Richard Schmuke
Topic: 19323 Message: 19358

Joe, I agree with you 100% , I have had a 15M alum antenna up in the air at different locations and the first installation was about 1980, in storage for a 7 year term and now back up , that makes it 24 years in the elements. The only problem was a resetting of the gama match last week, the point of resonance moved. Was it 24 years of corrosion??. Alum fence wire and 6061 tubing for antennas will hold up. I also have a 2m yagi I made with alum tubing and welding rod tips in use at a friends house, weather does not bother it except for the tree limbs during a storm. It was made with 1/4inch tubing, 10☐ long for center section and then tapped for 10-32 and heliarc rod threaded to fit the tubing. The ☐3/16 alum heli rods come in 36☐ lengths, a little short for a 2M beam so I incorporated a ☐1/4☐ center section Alum will hold up outdoors.

My statement was that the type 4043 mig welding wire I used was a disappointment for me. If I was going to buy some alum wire today I would use fence wire not type 4043 welding wire.

> Has anyone ever loaded up railroad tracks???

When you first asked this, I figured you meant abandoned tracks, of which there are plenty around here. Never considered live tracks. In a conflict with a moving train, the train usually wins.

Yes, I've heard of people loading up abandoned tracks. Even on VHF. One would think the low proximity (and possible ground wires at regular intervals, which I think I've seen on some tracks) might make it ineffective, but maybe not. Then again, you don't hear about people doing this a lot, so I'm guessing it is fun but not as good as a "real" antenna. And you might not want to use very much power, in case some kid half a mile down the tracks gets zapped by you.

This is really worthy of a different subject since it's not really about wire size anymore.

Andy

I had to replace my copper wire dipole in 2003 . after looking at the cost of copper wire I decided on 1/16" galvanize lift cable . has been up since december 03 and have not had any problems with it . still looks like the day it was put up . no rust or corrosion .
it is readily available in the USA at most any hardware or home improvement centre , don't know about across the pond . cost at that time was .06/ft . it is also a dull gray colour and if it was not for the end ropes it would be almost invisible .

It depends on weather or not is is strung tightly or supported by a weight VIA pulley.
I doubt if it will outlast copper wire, remember you can't solder to it so use split bolts and Anti-Ox.

I know there are going to be a number of negative comments but I just wanted to mention one of the strongest wires around. We used to call it Tanglefoot, or Trip Wire. It can be bought at Army/Navy surplus stores and online for between 2 and 7 dollars. It is 4 lengths of 38 foot 28 guage steel camouflaged wire which makes 152 feet in length. Steel isn't the best RF conductor, but I still find it strung as tanglefoot in the Army Training areas at Camp Shelby Mississippi. That makes it between 20 and 40 years old.

balun, waterproof the balun, and then waterproof the waterproofing. This

is

especially true here in the UK. lower antenna every year for maintenance.

It

is amazing the difference in SWR before and after. things deteriorate so

gradually you do not notice.

Unless the balun is very mechanically well built mount it on something UV

proof that will also have points to take strain of the antenna wire. I use

plastic guttering, if gently heated with hot air gun it becomes pliable

and

then flatten between heavy books etc. just drill out and away you go.

Have fun and hope to catch you on the bands

Jon

I had some friends who used jumper cables across tracks close to a RR
crossing. It would drop the arms then when they took the cables off the
arm
would go back up after a short bit. Like a train coming and going. They
got the idea from our Electronics teacher.

Don't do it!!! as ex railwayman it is something I actually know about.
signalling uses upto 600 volts DC/AC at various frequencies between rails,
in electrified areas most times return current path so could have upto 2KA
running through it. I suppose if you were in the middle of the Nullabor
desert or similar you may be OK but otherwise Don't do it even in jest.

Dean, that picture is showing two 1:1 baluns wired together to form a 4:1

Guanella current balun. The wire is not wrapped on PVC but it is 10MM

ferrite rods wrapped with a couple of layers of Teflon pipe tape and a wrap

of regular electrical tape at the ends to hold the Teflon in place while the

magnet wire is wrapped. The dual windings are spaced .025 with monofilament

fishing line then the assembly is has a light coat of quick drying epoxy to

hold it in place. The completed balun was then tweaked to a center frequency

of 10-MHz to give good coverage from 75M thru 10M. The next evolution of

this type is a indoor balun on 1/2” or 13MM ferrite rods to feed my 450 ohm

line and it is switchable between a 1:1 or a 4:1 balun setup. This can be

seen at http://s1102.photobucket.com/albums/g453/KD0ZZ/

Rich , Kd0zz CONTINUING SEARCH FOR PERFECT ANTENNA

Subject: Re: [ham-antennas] Thickness of HF wire antenna's

What is the diameter of the pvc the copper wires are wrapped around. It looks very nice. I do not have a balun on my antennas but I do have an RF choke just below each antenna. About 6 to 8 turns of coax about 10” in diameter.

19365. Re: [ham-antennas] Thickness of HF wire antenna's

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-21 17:34:00 UTC
From: dean
Topic: 19323 Message: 19365

There is a ham somewhat close to me, 50 miles or so who will not talk to me again. I have a good signal into the Turlock repeater here in California. He asked me how high my antenna was and I told him it was 2270 feet in the air. He was flabbergasted that I had an antenna that high. I told him it took me a week to raise it and then someone asked how high was the base of my antenna and I said 2250 Ft. He gave his call sign and I never heard him again. So funny.

I have a straight shot to Turlock’s repeater.

Some people have no sense of humor.

19367. Re: [ham-antennas] Cost of Aluminium wire

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-21 17:55:42 UTC
From: Joe
Topic: 19323 Message: 19367

I'm actually amazed as how well it does work.

It's fed with 300 ohm TV Twin lead to just before it enters the house
where a W2AU 4 to 1 balun is located which changes it to about 5 feet of
58 coax into a home brew tiner.

Rig 100 watt TS-430S
I'm happy with it. seems like almost any DX is one or two calls and I
got em. I'm actually having better luck with this thing than I did with
a 3 ele tribander at 60 feet.

Joe WB9SBD
Total Cost?

Free.

left over wire from a neighbor farmer.

ropes through trees,,, bailing twine. Only had to re string one in two
years. supoorts tall pine trees.

so the only cost was time everything else was either free or junk box
leftovers

I've seen it pretty cheap. Think I'll buy some! Thanks.

Subject: [ham-antennas] Antenna Wire

I know there are going to be a number of negative comments but I just
wanted to mention one of the strongest wires around. We used to call it
Tanglefoot, or Trip Wire. It can be bought at Army/Navy surplus stores and
online for between 2 and 7 dollars. It is 4 lengths of 38 foot 28 guage
steel camouflaged wire which makes 152 feet in length. Steel isn't the best
RF conductor, but I still find it strung as tanglefoot in the Army Training
areas at Camp Shelby Mississippi. That makes it between 20 and 40 years old.

From: Larry Tooley
Topic: 19323 Message: 19369

Quite true. I remember the ARRL Handbook saying a long wire becomes more directional off the end as the wavelengths get longer. No I don't want to mess up the electronics on the rail lines. I agree it may work but as stated, it is much better to real antenna.

> Has anyone ever loaded up railroad tracks???

When you first asked this, I figured you meant abandoned tracks, of which there are plenty around here. Never considered live tracks. In a conflict with a moving train, the train usually wins.

Yes, I've heard of people loading up abandoned tracks. Even on VHF. One would think the low proximity (and possible ground wires at regular intervals, which I think I've seen on some tracks) might make it ineffective, but maybe not. Then again, you don't hear about people doing this a lot, so I'm guessing it is fun but not as good as a "real" antenna. And you might not want to use very much power, in case some kid half a mile down the tracks gets zapped by you.

This is really worthy of a different subject since it's not really about wire size anymore.

Andy

19370. Can anyone explain this result?

Yahoo group: ham-antennas (2011-08 — 2011-12)

See the leaves starting to turn, and putting the final touches on my 160 vertical (http://www.bambinomusical.com/WB2HTO/Vertical.html)

Readings at the base of the antenna look like this, with an SWR and X minimum at my target f in the CW protion of the band, with a 1' piece of RG8X between the antenna and the MFJ259B:

SWR R X
1.770 1.9 38 27
1.780 1.8 37 24
1.790 1.7 36 19
1.800 1.6 35 15
1.810 1.5 35 11
1.820 1.4 35 5
1.830 1.4 35 4
1.840 1.4 35 7
1.850 1.5 35 10
1.860 1.6 36 14
1.870 1.7 37 19
1.880 1.8 36 25
1.890 1.9 37 29
1.900 2.1 36 37
1.910 2.2 36 39
1.920 2.4 35 45

But look at what happens when I take another set of measurements in the shack, which has about 12' - 15' of RG-8X coming from the base, under the porch and through the foundation into the shack, which is in the basement:

SWR R X
1.770 1.9 28 14
1.780 1.8 30 11
1.790 1.6 31 9
1.800 1.5 33 7
1.810 1.5 33 6
1.820 1.4 36 6
1.830 1.3 39 10
1.840 1.3 43 13
1.850 1.4 46 17
1.860 1.5 51 21
1.870 1.6 58 26
1.880 1.8 64 31
1.890 1.8 69 34
1.900 2 77 39
1.910 2.2 87 42
1.920 2.4 95 46

SWR and X are only slightly different, and both look good, right? But look what happened to R, it went from being flat to a low of 28 to a high of 95 (and that's not even the top of the band, yet.) Assuming that I know how to install PL-259 connectors and the coax is good....

- Was my base measurement faulty?
- Is the MFJ259B not accurate on 160?
- Should I care at all, since SWR and X are good?

Your thoughts?

David

My original reply must have been eaten...

When I was a teen, someone gave me an AN/CRT-3 transmitter - a survival transmitter used by the military and civilians from WWII through the 1960's. It was also known as a "Gibson Girl" transmitter.

The antenna was a long wire hoisted with either a kite or hydrogen baloon, both of which were included in the kit.

The antenna wire was some of the neatest stuff I'd ever seen. It was a copper braid wound over a nylon core. At maybe 20 AWG, it was extremely strong and nearly invisible. The stuff was impossible to solder as the nylon would melt on the attempt.

Any transmission line with a non-unity SWR, i.e. not 1:1, will act as an impedance transformer. The feedline length determines and SWR the amount of transformation. A half wavelength, or multiple thereof, will accurately mirror the complex impedance at the base of your antenna, but obviously only at one frequency.

I had a brand new AN/CRT-3 transmitter someone gave me when I was a teenager. Commonly known as the "Gibson Girl" transmitter, it was a survival radio meant to be carried on aircraft and saw service from WWII through the 1960's.

The antenna was a long wire and was meant to be raised with either a kite or hydrogen balloon, both included with the kit.

At any rate, the wire was the most amazing stuff I had ever seen. It was a copper braid wound over a nylon core. It was maybe 20 AWG and was strong as hell. A bit of a challenge to solder as the nylon would melt - it was meant to use used with mechanical connectors. Strong, lightweight and nearly invisible - great stuff if you can find it.

Topic: 19370 Message: 19376

Hi David...

I don't have much experience operating at 160m, but do check my antennas on that band. First... I often have problems because of broadcast stations in the area.... strange readings and sometimes the instrument just goes berserk and needs to be reset. If I try and listen on the band, it is a total overloaded mess unless I put my big tuner on line; the extra selectivity cuts the BCB overload and at least lets me hear. This is a recognized 160m problem, and MFJ used to sell a filter to eliminate BCB signal overload; they still may. Check the net, maybe you could make one. My qth is located in the suburbs of a metro area and there are many bc stations in the area.

The other time I've encountered strange readings with my antenna analyzer, the problem was cured by adding a choke balun on the cable between the meter and antenna. My choke was made from of a toroid core, but you could try winding some coax in a coil, or maybe around a paint can. It may not be the end solution, but should give you an indication of any rf coming back to the shack on the outside of the feedline.

Neither of those things may be a problem and the coax may just be giving you an impedance transformation.

Subject: [ham-antennas] Can anyone explain this result?

See the leaves starting to turn, and putting the final touches on my 160 vertical (http://www.bambinomusical.com/WB2HTO/Vertical.html)

Readings at the base of the antenna look like this, with an SWR and X minimum at my target f in the CW protion of the band, with a 1' piece of RG8X between the antenna and the MFJ259B:

SWR R X
1.770 1.9 38 27
1.780 1.8 37 24
1.790 1.7 36 19
1.800 1.6 35 15
1.810 1.5 35 11
1.820 1.4 35 5
1.830 1.4 35 4
1.840 1.4 35 7
1.850 1.5 35 10
1.860 1.6 36 14
1.870 1.7 37 19

1.880 1.8 36 25
1.890 1.9 37 29
1.900 2.1 36 37
1.910 2.2 36 39
1.920 2.4 35 45

But look at what happens when I take another set of measurements in the shack, which has about 12' - 15' of RG-8X coming from the base, under the porch and through the foundation into the shack, which is in the basement:

SWR R X
1.770 1.9 28 14
1.780 1.8 30 11
1.790 1.6 31 9
1.800 1.5 33 7
1.810 1.5 33 6
1.820 1.4 36 6
1.830 1.3 39 10
1.840 1.3 43 13
1.850 1.4 46 17
1.860 1.5 51 21
1.870 1.6 58 26
1.880 1.8 64 31
1.890 1.8 69 34
1.900 2 77 39
1.910 2.2 87 42
1.920 2.4 95 46

SWR and X are only slightly different, and both look good, right? But look what happened to R, it went from being flat to a low of 28 to a high of 95 (and that's not even the top of the band, yet.) Assuming that I know how to install PL-259 connectors and the coax is good....

- Was my base measurement faulty?
- Is the MFJ259B not accurate on 160?
- Should I care at all, since SWR and X are good?

Your thoughts?

Topic: 19370 Message: 19377

The length of coax does a complex impedance transformation. On a Smith chart it is a rotation part-way around the chart. It can profoundly alter both R and X. A larger R does NOT mean you made a bad solder connection anywhere, nor that anything is wrong.

On one side of the Smith chart, the R values are smaller. On the other side they are larger, even though the SWR is the same (or a little less). Rotating around the Smith chart, with a constant radius, can move you from the small-R region into the large-R region, as a function of frequency. That's just how transmission lines work. T'is normal.

I had a 160 meter vertical where I used to live.
There was an am radio station nearby and the mfj259 gave me erroneous readings due to the interference from the radio station.
But I was able to characterize the impedance of the antenna using a mfj noise bridge.
I am not saying that is your situation because the readings you have shown actually look quite good.

Having completed a long railroad career, where I came into contact with all kinds of rails on a daily basis, even sitting on them in the rain, I can assure you that I have never encountered even the slightest presence of voltage, not even at crossings. Where would I find the voltages and currents you are refering to?

The best reason for not using railroad tracks is because tampering with railroad equipment is a federal offense, and if you are unlucky enough to be caught by railroad police or FRA inpsectors, and you have equipment connected to the rails, you will certainly be given the chance to see if you can load up steel bars.

I am NOT the original poster, but the "third rail" is the only place that I can think of. (A power rail for electrified locomotives.)
Barring those there is only enough Voltage to pull in a relay to activate the signals.

The important aspects of this thread is two parallel rails look more like a open wire transmission line than an antenna, not being insulated the wet wooden or concrete ties (sleepers)
would absorb the energy pretty fast. Also:
The top three most important things about antennas are 1. location 2. location and 3. location and
down on the ground is not up high in the air.

I couldn't agree more with the fed's getting involved if someone tampers with rail equipment.

I spent about two hours being questioned by a couple of FBI agents when a piece of railroad communications equipment disappeared from a rail car parked near a small business my Dad owned. I used to do a lot of work around the place for him and I was surprised that I was a prime suspect and it took some effort to convince them that I had nothing to do with the equipments disappearance. Seems like my ham license and my immediate proximity to the alleged crime lead them to my front door, at least that's what they suggested during our lengthy conversation.

Here in the UK the signals are controlled as I describe although inductive loop and RFID is now becoming more common especially on high speed lines and yes the traction return current does run through the rails.. Honest

From: AB2ZY
Topic: 19323 Message: 19383

This is straying far afield from antennas...

In the US, most of the block signaling and crossing control is implemented via low voltage on the tracks and shunting the rails.

Trying to use railroad tracks as anything other than a VLF antenna is a dumb idea for an uncountable host of reasons.

If memory serve me well (it often does not) that wire was called "Litz" wire. And like you say it was part of the Gibson Girl package. Wonderful wire, aggravated me to no end while trying to solder on to it!
I used the stuff for many assorted antenna projects, it used to be easy to find at the electronics surplus places in and around the S.F. Bay Area in 60's and 70's.
Wish I still had a bunch, 'specially at the prices we used to pay for it 40-50 years ago, even back then it was a steal.

It can be bought at Army/Navy surplus stores and online for between 2 and 7 dollars. It is 4 lengths of 38 foot 28 guage steel camouflaged wire which makes 152 feet in length. Steel isn't the best RF conductor, but I still find it strung as tanglefoot in the Army Training areas at Camp Shelby Mississippi. That makes it between 20 and 40 years old.

I am NOT the original poster, but the "third rail" is the only place that I can think of. (A power rail for electrified locomotives.)
Barring those there is only enough Voltage to pull in a relay to activate the signals.

The important aspects of this thread is two parallel rails look more like a open wire transmission line than an antenna, not being insulated the wet wooden or concrete ties (sleepers)
would absorb the energy pretty fast. Also:
The top three most important things about antennas are 1. location 2. location and 3. location and
down on the ground is not up high in the air.

HI ALL<

I have a 130Ft doublet at 26Ft , this is made from 1.5mmmSQ insulated wire from a 15amp extension lead, the open wire feeder is from the same material, and cut to a 1/4 wave at 7Mhz,.

as far as I am aware the dia of the wire will not have a great bearing on the performance of the antenna,I have built J poles out of 3.2mm brazing rod instead of the 12mm copper pipe specified without any issues in performance.

As long as the wire is electrically conductive, with minimal resistance (not s/steel), and is able to support it's own weight for the length of the antenna, you should not have any problems,insulated wire would be better as the insulation will provide protection to the wire from the elements, be sure to seal all connections.

Cheers from downunder,

Jeff

> If memory serve me well (it often does not) that wire was called "Litz" wire.

I'm no expert here. But just wanted to say that I think Litz wire is something else.

Litz wire is composed of multiple, individually insulated, very fine strands, arranged in a special way. It is supposed to yield low AC impedance (compared to a solid or ordinary stranded wire) over certain frequency ranges, generally up to the MF or lower HF bands, from what I've read. It is not known for any special mechanical strength. And Litz wire is supposed to be easy to solder, since the thin insulations easily burn away.

This one with the strong nylon core sounds different.

Andy

Correct Andy, the stuff with the nylon core (could also be cotton) is called Tinsel Wire.

Normally it is crimped, unstripped into an open barrel lug with spikes which pierce the insulation making contact with the wire. Look at the leads of an old, old telephone handset cord, one with spade lugs on it.

While it is tricky, it can be soldered to by taking several strands from a fine wire source, like those scavenged from a piece of lamp cord (aka zip cord).

Wrap the lamp cord strands around the stripped tinsel strands (making what looks like a spring) leaving a pigtail and quickly solder. The pigtail then can be soldered to whatever you need to connect it to.

While it doesn't look too pretty, unless you add some shrink tubing, the technique does work... just takes a bit of practice, but then doesn't everything? ;-)

Stan

On L.B. Cebik's website (http://www.cebik.com, free registration needed to access), there is a page about antenna wire materials. Look for "A Note on Wire Size and Material."

He has a table showing the difference between 14 AWG stainless steel and a superconductor, is less than 1 dB for a 40m dipole.

Another table has data on wires going down to 24 AWG copper, with less than 10% loss in efficiency.

This stuff was considerably thicker than the tinsel wire you'd find in a telephone, but you've got the idea of how it was constructed.

Here are a couple of links where you can see the thing in action. The kite was not small and the wire had to withstand a fair amount of wind load.

Longest first. I had to do this with my 5 band dipole. How are you spacing your elements? I used dabs of epoxy to hold my PVC strips in place then after a winter of wind, snow and ice some of the epoxy came loose and the spacers slid together. I then reset my spacers and soldered them in place with a small length of 22ga wire.

Topic: 19392 Message: 19395

I use a fan dipole (picture on QRZ) which has 80/40 legs in parallel running north/south and 20/17 in parallel running east/west, which makes the system self-guying. Recently I trimmed each of them for a better match in the cw portions and started with the 80m leg first, then worked down to the 17m. I've done it other ways and if there is a difference, I can't tell it, but as a practical matter, it is easier to start with the longest leg. The only thing I can discern about tuning a fan is that you have a narrower bandwidth that if you use individual ones.

The longest really must be tuned first -- then the shortest. Trust me, based on experience and everything else I have read.

19397. Re: [ham-antennas] RFI Tripping GFI Outlet

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-24 15:14:37 UTC
From: Frank Kirschner
Topic: 19397 Message: 19397

I occasionally have a GFI outlet in the house trip when using the amplifier on 15 meters. It only happens on that band and with the amp. It happens to be the outlet to which my Internet connection gets its power, so it's kind of important.

I was thinking of bypassing the outlet with some low-value capacitors, but there's a possibility that the capacitors themselves would allow a small amount of ground return current, thus tripping the interrupter.

Any suggestions?

Thanks.

Actually you want to start with the longest dipole first and then work your way to shortest. You can Google tuning a Fan Dipole and learn all you need to know about doing this. It's easier with an antenna analyzer, but it can be done with the cut and hunt method too, it just takes longer.

I've done this many times and it is much easier to start with the lowest frequency antenna and work your way to the highest frequency antenna.

Here's a link to get you started.

http://www.hamuniverse.com/multidipole.html

Keep us posted on your progress, although it can be a time consuming process, if you take your time it can be accomplished without to much pruning.

From: Larry Tooley
Topic: 19397 Message: 19400

I wonder if that is RF on the line that makes the GFI sense the umbalance.
It think's it is 60 hZ leakage.

Subject: Re: [ham-antennas] RFI Tripping GFI Outlet

I occasionally have a GFI outlet in the house trip when using the
amplifier
on 15 meters. It only happens on that band and with the amp. It happens to
be the outlet to which my Internet connection gets its power, so it's kind
of important.

I was thinking of bypassing the outlet with some low-value capacitors, but
there's a possibility that the capacitors themselves would allow a small
amount of ground return current, thus tripping the interrupter.

Any suggestions?

Thanks.

That's what I'm thinking. I'm just not sure if bypass capacitors would alleviate or exacerbate the problem.

Hi Frank...

Have you tried a new GFI? Might be cheaper than trying to add rf suppressors to the line. Personally, I don't like to modify items like that... just a reason to have someone cancel your insurance it there's an electrical fire.

Might try and build the caps into an ac plug, and just stick it into one of the outlets... see if it helps.

From: AB2ZY
Topic: 19397 Message: 19403

GFI devices sense the current balance between the neutral and hot leads. If the balance is not equal to zero, that means that there is path for return current outside the neutral and the device will trip.

Adding bypass capacitors would likely cause the device to trip.

There is some fairly sensitive electronics inside the outlet and your RFI problem may not necessaily be caused by interference conducted through the power lines acting as an antenna. Here are 5 things to try, in ascending order of cost and complexity:

1. Put a toroid on any power cords plugged into the outlet close to the plug.
2. Pass the connection wires inside the box through some toroids.
3. Replace the GFI outlet with a different brand.
4. Find a way to shield the GFI outlet. A metal instead of plastic box perhaps.
5. Replace outlet with a standard duplex and change circuit breaker in distribution panel to GFCI type. These tend to be expensive. A 15A standard circuit breaker and GFCI outlet might cost a total of $12 or so. A GFCI breaker will run $35 or more.

had one that tripped on 20 metres it powered a refrigerator and CO detector and the CO detector beeped whenever it lost power so I knew when I had to go and reset it . tried several different brands and none solved the problem . it may have been the length of the romex was a good 20 metre antenna .if you solve the problem let everyone know what you had to do .

I use a fan dipole (picture on QRZ) which has 80/40 legs in parallel running north/south and 20/17 in parallel running east/west, which makes the system self-guying. Recently I trimmed each of them for a better match in the cw portions and started with the 80m leg first, then worked down to the 17m. I've done it other ways and if there is a difference, I can't tell it, but as a practical matter, it is easier to start with the longest leg. The only thing I can discern about tuning a fan is that you have a narrower bandwidth that if you use individual ones.

If you are referring to the FT-101ZD, I bought it new in April 1979, one month after they came out. It is almost new now, even after 32 years, because I used it lightly until 1983, then dropped out of radio for 25 years until 2008. Even after coming back, I seldom used it, using my new K1 instead, then last year I bought the FT-950, so the FT-101ZD is actually a new-old radio.

I have an 80 meter doublet fed with 40 feet of ladderline and 10 feet of rg-8. I have palomar bead balun at the end of the coax. The problem is that occasionally the antenna will not tune a band. Sometimes it is 80 meters sometimes it is 40/15 meters. I have used two swr meters and get the same results. I replaced the coax last time and thought I had fixed the problem. But it is back. I have checked all the solder joints (resoldered) and the seem to be okay.

What do I look for next?
Thanks

Jeff

Hello Jeff,
Well for starters I would check your ladderline. Most of the ladder line made is usually 18 awg and it is solid. As the ladderline whips around in the wind it breaks. It is hard to find because it breaks inside the insulation. So the result is it makes contact sometimes and the other times it is not. You can get ladderline that is stranded and holds up much better. Hope this helps.

From: Rui Martins
Topic: 19417 Message: 19417

Hi,

I have one Emotator Rotor which I think is a 14c.

I don't have command and manual.

Can anyone help with this manual?

I did not see anything on a model 14C but I did see this web page

http://www.rigpix.com/rotators/rotators.htm

of which covers model's 103LBX, 502CXX, 1102MXX, 1103MXX, and they have listed but no info on 1105FXX and 1200FXX.

and this page which lists two units not mentioned on the last one.

http://www.mods.dk/manual.php?brand=_other

This might help also but without the info on the plate its like shooting fish with a bb gun after dark.

19421. Ham Stick Antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-25 17:57:46 UTC
From: ken.k6kaw@gmail.com
Topic: 19421 Message: 19421

What can I do to improve the receive performance of these antennas? I know operating on verticals is inherently noisy but there has to be a way of moderating this high noise...

I also know that the front end of my radio is not the best < FT-857d >. How about a Capacity Hat. And how would I go about that?

From: kd8phx
Topic: 19397 Message: 19425

What kind of amperage is being drawn thru this GFI? If you are getting close to the rating, it will pop & especially if it is old. I have seen this & replacing the old one fixed the issue. GFI's do some weird things. I replace it with a 20AMP GFI since 12ga wire was attached to it.

From: jo barden
Topic: 19421 Message: 19426

Depending on the frequency you are using perhaps co-phasing may be an option, you wil get gain and reduced signal from the sides so the noise levels from there will be reduced, depending on frequency though you might have a bit of coax to coil up!

Ken
Capacity hats are for top loading to shorten an unweildy long antenna. That will not solve a noise problem.
What is the source of the noise? if it is atmospheric, there is nothing you can do about it. If it is manmade, some types of noise can be killed with the radio's noise blanker. Such as repetitive noise from ignition systems. If it is YOUR ignition system you can install filters on the 12 VDC battery line.
There is no reason to believe that your receiver is not good. Yaesu radios historically have excellent receivers in terms of sensitivity.

Well it is now up at a friend house (Kc0ziu) so I can't run and check the spacing but if I remember it is about 1.8" to 2". I took a scrap length of PVC conduit and split it into 4 segments with a scroll saw. It worked fine as a fan dipole. The closer you have the wires the more they will interact. It has been replaced with a Delta loop and I am very happy with the loop. The dipole is directional and I get much better coverage and better overall signal reports with the loop.

Try this site for grounding ideas

http://www.k0bg.com/

He doesn’t like the K 400 but I do and my Elmer has them and they work for him.

I got the sierra slims from High Sierra and they seem to be better than the ham stick.

I’m use mostly the 20 meter Sierra Slim and I got noise but I have made contacts to ND, Montana, CO, MN and others. I live in tree country so if I was on the flatlands I probably could make more contacts. My vehicle is a lot of plastic. I was just a tech when I bought the Vue so I have to suffer with less of a ground plane. My mount is a K 400 3/8 connector. I’m going to replace my 1/2 “ grounding strap with a 1” one. I use lots of Ferrite cores close to the radio and on my power connector. The only thing that does not have a ferrite core is the mic and the VHF/UHF antenna.

Its still noisy but I live with it and it works.

Yah the loop is far better but the only place I can put the loop is over my house. When the tv has problems when I transmit the wife will do horrible things to my equipment. She puts up with all my antennas so long as they are in the back yard.

How far apart are your spacers from one another. I think I would like to make one for 75, 40, 20, 17, 15, 12, and 10. I can only put it up about 44 Ft.

19432. how to connect 450 ladderline to coax

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-25 19:41:03 UTC
From: elbertm
Topic: 19432 Message: 19432

Hello to everyone.

I am new to using 450 ladderline and need info on how to connect or splice the line to the coax.

I plan on building a 80 meter dipole (inverted v) and using 450 ladderline up to the shack then connect to coax, to inter the building.

Will I need some type of balun and where would I install it?

If there is a web page somewhere on the internet that shows all of this, I would appreciate it.

I have an auto tuner.

Any info, etc. will be appreciated.
Thanks
KC4YFA

IMHO I would keep the coax run as short as possible. If you have high SWR and long coax you will have more loss, the longer the coax.

Coax is a unbalanced line and 450 ladder line is a balanced feed so it will require a balun at the ladder line to coax intersection. Will you require a 4:1 balun (most likely) or a 1:1 balun? That depends on you length of 450 ohm line with your set up.

Not much. The only thing plugged in is the Verizon FIOS box. This provides
TV and Internet connection. I'm guessing < 2A.

I have a 102-ft doublet (probably shorter than your 80 M dipole) fed with 450-ohm ladder line. I run the ladder line to a 9:1 balun, thence to a short run of coax to the antenna tuner. I also tried a 4:1 balun, with essentially identical results. (Slightly different numbers, but no better or worse.) I stuck with the 9:1 because it is easier to mount and connect to.

I work all bands from 80 to 6 with fairly low SWR (except 15, which doesn't tune at all well).

Hope that helps.

Gentlemen , I looked at a 9:1 balun but saw that a lot of people run a 4:1 and some a 1:1 balun. Because I like to make my own things I made two, 1:1 rod type baluns side by side and then made it switchable between a 1:1 or a 4:1 balun. It was easier to do it this way than use a 9:1 and make it switchable. My switchable balun is inside on my windowsill then to the 450 ohm window feed thru.

Well Ken... you can't use 50 radials on your car when driving... I know this for a fact. However, have you ever seen the Red Green Show on PBS? You ever see the episode were he used duct tape to put 6 or 8 cars together, so everyone could "car pool", but still use their own car? Much better chance of using radials in that situation if you can find a couple of neighbor hams going in the same direction!

On a more serious note, how much does the noise level change in the radio after the car is started? That is the noise you should be able to eliminate further by panel bonding, electrical bypassing, and filtering of various electrics in the vehicle. Anything that is there before the car is started is atmospheric rf; noise level should be the same on a vertical on a fixed station at that location, maybe even higher with a larger vertical. Radials make an antenna more efficient... so noise levels will increase in signal strength.... nature of the beast.

Wrong end, how about a hundred radials? How about putting it up over your house.

Hi...

I've always liked this design... never built one, and probably never will... but I like it.

http://www.w5dxp.com/notuner.htm

If you've got the trees and some space for the ladderline, it looks really good.

I have a large roll of RG-8X on my back porch. I think I'll put an "UGLY BALUN" http://www.hamuniverse.com/balun.html at the end of the coax. Not even sure if it'll make a difference but it'll be fun making it.

No 450 ohm ladder line but I do like this dipole. I’m thinking of building it but first I have to sweet talk the XYL out of the $$$$ for the wire.

Just doing some checking on the internet I come up with these sites for some help.

http://www.bencher.com/ham/index.php?main_page=page_4

http://forums.qrz.com/showthread.php?295215-Vertical-Antenna-with-NO-radials

http://www.eham.net/reviews/detail/1902

I had the R7 and it did not require guying or radials. I live in California and I talked to Spain and Poland on it and of course other places. When I got my Beam and dipole I gave it to a friend and I wish I hadn't now.

http://www.cushcraftamateur.com/Product.php?productid=R8

http://www.universal-radio.com/catalog/hamants/4287.html

only problem I can see with the Cushcraft is no 80 meters.

http://www.universal-radio.com/catalog/hamants/4778.html

Sorry that I can only give you web pages as I now only have dipoles (I live on 8 acres).

Enjoy

Hi Jim,

I wish you good luck in this endeavor... As far as I know the only thing that is close is a vertical dipole, and that only operates on one band...

I also wanted an antenna like that, but have not been able to find it. The closest I have found is a Gap Challenger. Works fine, has only three radials, and in theory does not need guys. I have added guys, but they say it does not need them.

Jim

I have been using a HyGain AV-640 for years and it really works well. It is a 3/8 wave vertical which has low angle takeoff for DXing. No radials to lay on the ground.

19446. Inverted V vs (end fed) Sloper Antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-26 20:13:10 UTC
From: rrath
Topic: 19446 Message: 19446

What is the performance difference between
the Inverted V and the end fed Sloper
antennas?

Is one better than the other in a high noise
(RFI) (10 to 20db) area? (80 meter band)

Thank you.
Rod kc7vqr

Dean, a “Ugly Balun” did help the loops at K2HT and KD0ZZ’s, it brought the SWR down a little at each place. We use about 5 or 6 turns of RG-8X with a little tape right below the balun. I added a tie-wrap around the ugly balun and then back up to the balun box so it did not load the coax. Below the balun it changes to RG-8 with solid dielectric so it is heavy.

Subject: Re: [ham-antennas] Ham Stick Antennas

I have a large roll of RG-8X on my back porch. I think I’ll put an “UGLY BALUN” http://www.hamuniverse.com/balun.html at the end of the coax. Not even sure if it’ll make a difference but it’ll be fun making it.

Well Ken... you can't use 50 radials on your car when driving... I know this for a fact. However, have you ever seen the Red Green Show on PBS? You ever see the episode were he used duct tape to put 6 or 8 cars together, so everyone could "car pool", but still use their own car? Much better chance of using radials in that situation if you can find a couple of neighbor hams going in the same direction!

On a more serious note, how much does the noise level change in the radio after the car is started? That is the noise you should be able to eliminate further by panel bonding, electrical bypassing, and filtering of various electrics in the vehicle. Anything that is there before the car is started is atmospheric rf; noise level should be the same on a vertical on a fixed station at that location, maybe even higher with a larger vertical. Radials make an antenna more efficient... so noise levels will increase in signal strength.... nature of the beast.

Wrong end, how about a hundred radials? How about putting it up over your
house.

19448. RE: [ham-antennas] Re: how to connect 450 ladderline to coax

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-26 20:58:25 UTC
From: Richard Schmuke
Topic: 19432 Message: 19448

I made it and it works fine. I did not space mine far apart on the ends because I needed the spacers to keep the wires from twisting in the high wind we get here.
http://i1102.photobucket.com/albums/g453/KD0ZZ/DSC00947.jpg

If you zoom in on the picture you will see a dipole center support and RG-8 coax holder that requires no clamp. Tell the XYL you are making a variable length resting perch for the birds.

Rich , Kd0zz

Subject: Re: [ham-antennas] Re: how to connect 450 ladderline to coax

No 450 ohm ladder line but I do like this dipole. I’m thinking of building it but first I have to sweet talk the XYL out of the $$$$ for the wire.

Hi...

I've always liked this design... never built one, and probably never will... but I like it.

http://www.w5dxp.com/notuner.htm

If you've got the trees and some space for the ladderline, it looks really good.

actually can do it with the aluminum window alarm tape or the self adhesive copper tape used by stained glass people and gardeners (stops slugs climbing up stem when a bit is put on stem) my wife is keen gardener.

The window alarm tape is an old dodge to get stealth antenna on window and comes with terminal posts to connect to.

Hi,

Any one has got any experience with “chameleon V4” antenna on portable.

Can it tune to 40m & 20m too (can be seen in some youtube videos) !!...the specs say can work from 20 MHz to 300 MHz only.

Any views ?

Date: 2011-08-27 03:03:22 UTC
From: jayzap57
Topic: 19456 Message: 19456

I'm installing a DXE 43ft vertical with an Icom AH-4 tuner at the base.
Would it be a good idea to wind a choke right before the tuner ??

The coax the feeds back to the shack underground is RG213, would it mater if the connection from the antenna to the feed into the house is RG-8 or if I use a choke I make it from RG-8.

Don't have anymore RG213 and this project is replacing a Butternut vertical which used a peice of RG-11 as a matching section so the RG213 does not reach where the DXE will be.

Thanks Jay N1FDX

Gentlemen , I looked at a 9:1 balun but saw that a lot of people run a 4:1 and some a 1:1 balun. Because I like to make my own things I made two, 1:1 rod type baluns side by side and then made it switchable between a 1:1 or a
4:1 balun. It was easier to do it this way than use a 9:1 and make it switchable. My switchable balun is inside on my windowsill then to the 450 ohm window feed thru.

Rich , Kd0zz

Subject: Re: [ham-antennas] how to connect 450 ladderline to coax

I have a 102-ft doublet (probably shorter than your 80 M dipole) fed with 450-ohm ladder line. I run the ladder line to a 9:1 balun, thence to a short run of coax to the antenna tuner. I also tried a 4:1 balun, with essentially identical results. (Slightly different numbers, but no better or worse.) I stuck with the 9:1 because it is easier to mount and connect to.

I work all bands from 80 to 6 with fairly low SWR (except 15, which doesn't
tune at all well).

Hope that helps.

No choke between the tuner and the antenna, but you will need to choke both the input coax and the control cable, at least that's been my experience with the AH-4.

Hi Sigi

Snails and Slugs get a shock from the copper so yes any coax sheilding etc
would work, it doesn't work with cabbage white butterfly caterpillars though
as we have loads of them!

19467. RE: [ham-antennas] how to connect 450 ladderline to coax

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-27 12:21:48 UTC
From: Richard Schmuke
Topic: 19432 Message: 19467

The switchable balun is between my tuner and window feed thru. Checked all the bands, I picked which setting work best for each band, added that information to my amp tuning chart. The built in balun in my MFJ tuner did not get 1:1 on all the bands so I made my own. The balun is shown at the following links.

http://i1102.photobucket.com/albums/g453/KD0ZZ/4to11to11.jpg

Sent: Thursday, August 25, 2011 7:40 PM
Subject: RE: [ham-antennas] how to connect 450 ladderline to coax

Gentlemen , I looked at a 9:1 balun but saw that a lot of people run a 4:1 and some a 1:1 balun. Because I like to make my own things I made two, 1:1 rod type baluns side by side and then made it switchable between a 1:1 or a
4:1 balun. It was easier to do it this way than use a 9:1 and make it switchable. My switchable balun is inside on my windowsill then to the 450 ohm window feed thru.

Rich , Kd0zz

Subject: Re: [ham-antennas] how to connect 450 ladderline to coax

I have a 102-ft doublet (probably shorter than your 80 M dipole) fed with 450-ohm ladder line. I run the ladder line to a 9:1 balun, thence to a short run of coax to the antenna tuner. I also tried a 4:1 balun, with essentially identical results. (Slightly different numbers, but no better or worse.) I stuck with the 9:1 because it is easier to mount and connect to.

I work all bands from 80 to 6 with fairly low SWR (except 15, which doesn't

tune at all well).

Hope that helps.

Rich, you dated yourself. Original tape used to seal duct work in what was only heating at that time was asbestos based that was pasted on. Later came the sticky grey duct tape common for HVAC uses. I remember when the aluminum tape came out. What a wonderful thing is is, and looks professional to boot. I had heard the story about "duck" tape originated for use on Army Ducks but always thought the imported Duck tape was a misspelling because most people pronounced "duct" tape that way. Any way, just a little more info.

19469. RE: [ham-antennas] Re: 43' vertical antenna project questions

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-27 12:57:53 UTC
From: Jay
Topic: 19456 Message: 19469

The Butternut was not a bad antenna at all. It was very narrow on 75-80 which was to be expected but the tuner in the rig would not make up for it so I had to stick to either the Phone or CW part of the that band. Seem to work Ok on most of the other bands. I made the W5GI Mystery antenna http://www.iw5edi.com/technical-articles/w5gi-mystery-antenna and it seem to perform as well or better most of the time on all bands. The tuner in the rig tune all of 75-80m and it cost me nothing to build, the Butternut was $460.

As for the construction it is a bit lightweight for the New England winters, it had me really worried last winter.

So anyway I owned an Icom AH-4 remote tuner so I thought I would give something else I try. After reading the reviews on the 43ft vertical it seems like they working well on 20m on down.

That’s my story. Hope it’s not a mistake, we’ll see once it’s up.

Well, we swerved a little bit when we went to Red Green and duct tape, but the latest couple of ideas are pretty good. Some sort of aluminum or copper tape over a small diameter rope would make a strong and light emergency antenna... don't know how long it would hold up in the weather. Might even be able to use surveyors string ... its cheap, light, and very strong for its size; parachute cord would be another candidate. Aluminum tape is commonly sold in hardware stores for sealing duct work.

actually can do it with the aluminum window alarm tape or the self adhesive copper tape used by stained glass people and gardeners (stops slugs climbing up stem when a bit is put on stem) my wife is keen gardener.

The window alarm tape is an old dodge to get stealth antenna on window and comes with terminal posts to connect to.

Duct tape dipole anyone? Easy to trim, just tear off a few inches.

Nice idea, Van. I like that idea better than the foil tapes... common materials used in an uncommon way. Do it over some cord and it would be a very portable and flexible emergency antenna... Jim, K9JFK

Sure, just stick a strip of aluminum foil to the duct
tape, run to a center insulator, and away you go. A
tear off antenna.

What's wrong with plain old No. 14 stranded copper wire that was left over from that last job, then we rolled it up and threw it over in the corner of our workshop? Don't everyone have that kind of stuff lying around? So we're back to a simple wire dipole---what could be simpler?

Don't know hw far back the good old days go back for you...for mw they go back to the spring of '66 when WN5PSE first went on the air.

I vaguely remember those maps, but, cannot recall how reliable they were.

I have an iPhone app that takes me to http://www.hamqsl.com/solar.html

Paul has a pretty darned informative website that offers realtime monitoring of a multitude of atmospheric and solar observations and even a summary of current conditions as related to ham bands/MUF...although, I suspect it probably can.

For that, I keep an eye on a dx reflector filtered to just display results for six.

Let us know if you find something...Mike, WA5PSE

19479. Re: [ham-antennas] 43' vertical antenna project questions

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-27 15:45:02 UTC
From: James Irving
Topic: 19456 Message: 19479

Hi Jay...

I used to think the air wound choke solution was adequate for keeping rf off the transmission line. After installing my antenna 150ft from the house, I wanted another solution.... found it here at the web pages of Steve, G3TXQ....

http://www.karinya.net/g3txq/chokes/

Look at the reactive impedance of the air chokes versus the resistive impedance of 43 or 31 mix ferrites. I am using 8 beads of 31mix over an rg213 sized coax. That doesn't mean I haven't, or wouldn't use an air wound choke; I just view it as a single band solution. Another reason I switched to ferrites was to reduce additional coax losses caused by increasing the length through air baluns.

I've got the beads at both ends of the transmission line even though it is buried in pvc conduit a foot down. After the installation, my first surprise was the vertical was "quiet". Don't know if that is because of the beads stopping rf shield pick-up or the buried coax, but its a "show stopper". Another ham a couple of miles away often comments on the noise p/u of his vertical and having to switch to his dipole. More often than not, my response is "What noise?"

BTW... Steve is well known for his work on the hexbeam and a tour of those pages makes for good reading....http://www.karinya.net/g3txq/hexbeam/

Subject: [ham-antennas] 43' vertical antenna project questions

I'm installing a DXE 43ft vertical with an Icom AH-4 tuner at the base.
Would it be a good idea to wind a choke right before the tuner ??

The coax the feeds back to the shack underground is RG213, would it mater if the connection from the antenna to the feed into the house is RG-8 or if I use a choke I make it from RG-8.

Don't have anymore RG213 and this project is replacing a Butternut vertical which used a peice of RG-11 as a matching section so the RG213 does not reach where the DXE will be.

Thanks Jay N1FDX

Hi Joe.
I use this small free one from G4ILO http://www.g4ilo.com/voaprop.html

It's very good and gives a reasonable idea of what is happening. The only problem I find is that its size is dependent on the screen resolution which you have set, but then again a lot of programs have that problem!

Wellllll..... there's nothing wrong with that... the other was just a short discussion of a "thought experiment." Personally, I absolutely hate some type of wire antennas! Copperweld... now there's a wire from hell! Just trying to keep it straight seems to be an exercise to check your patience and sanity.... one or the other is sure to go, especially if you don't have a helper at the other end. Even the smallest gauges seem to need 100lbs on one end to keep it from springing back to a coil... and the other end needs the strength of a good oak tree to hold it!

Nothing wrong with #14 stranded, or even #16, just need a couple of trees to hold up the ends. I always seem to be one tree short, no matter where I live....

I think I've seen that graphic, I guess the air wound is limited. I'm not sure what "8 beads of 31mix" actually means or what or were to buy them. I do have some clamp on style chokes, look like magnet material that I was going to put on the control cable.

I'm mounting the tuner in a plastic enclosure which has plenty of room and had thought about putting a MFJ-915 isolator http://www.mfjenterprises.com/Product.php?productid=MFJ-915 right at the tuner in the box with a short pigtail of RG58 or 8X. Do you think this suits that purpose ?

From: applewiz2000
Topic: 19432 Message: 19483

Sorry for late answer...

Why use 450 ohm to feed an inverted V dipole? The dipole will have impedance 50-70 ohms, a big mismatch. IMO better to use the ant as a doublet, make a 1:1 and fit your ATU between the 450 ohm and the coax.

The auto tuner then matches the 450 ohm to the 50 ohm, and the 1:1 gives you the balance.

I thought the public buildings were suppose to be manned by 2 meter operators that pass traffic
to HAMs in nearby houses with dipoles and beam antennas on the HF bands. That's the only way I have
heard of it being done here in Florida.

As mentioned earlier on this list server there exists a braided cord with stranded copper wire
braided within. The wires can be cut and removed from a point and on. This sounds perfect for
temporary, portable and emergency antennas that would need no end insulators. I would love to build
a complete set for every band with one feedline and balun making a dipole.
(attached with a nut onto bolts on the balun, with sturdy eye lugs on the inner ends of the wires)

The proposed antenna will work just fine, this mismatch at the antenna is insignificant and as
long as there is a balun at the open wire feedline to coax interface there will be no problem.

How dare you insult me and call me old, I am a young man! Until I look in the mirror, then I get scared.

I have used a lot of the alum tape. Have you ever seen a Tesla coil? On the top is a round donut shaped torrid. 6” form 30” dia, It is a large capacitor hat, I have made them with flexible PVC drain pipe then cover it with a couple of layers of alum tape, trying to make it smooth. It then becomes a capacitor on the top of the antenna at 200,000 volts, sort of a spark gap transmitter at low frequency. So I think real alum “duct” tape would work as a antenna.

Yeah I know I am nuts but is more fun than being in control of your facilities.

Rich , KDØZZ , ☺

You're just jealous because the voices only talk to me.

Rich, you dated yourself. Original tape used to seal duct work in what was only heating at that time was asbestos based that was pasted on. Later came the sticky grey duct tape common for HVAC uses. I remember when the aluminum tape came out. What a wonderful thing is is, and looks professional to boot. I had heard the story about "duck" tape originated for use on Army Ducks but always thought the imported Duck tape was a misspelling because most people pronounced "duct" tape that way. Any way, just a little more info.

Joe,

If you're looking for HF sites, there are many sites that are really great. Some you already know about; others you can find by just Googling.

There is one GREAT site that I know of that focuses on VHF/UHF propagation:

http://www.dxinfocentre.com/tropo_wam.html

Hope this helps.

But I hope someone can help me here.

I remember in the "Old Days" QST used to have these predicted
propagation maps. It was like where you can look and estimate when the
best time would be to talk to like europe or Hawaii or whatever.

I bet there is something like this online now. anyone know where?

Hi Ron...

I'm "frugal." If we are talking about the "tinsel wire", as in
....http://www.rajasthanelectric.com/Tinsel_Copper_Wire.htm
I probably wouldn't be interested. Description says it's made from thin copper foil, and if you want it, they'll furnish you with a quote. Sounds to expensive for a "frugal" ham like me!

Much easier to try it out with surveyors cord, duct tape, and aluminum foil. Probably won't look as good, but should be cheap to repair or replace.

Then again, is a copper or stainless steel kitchen scouring pad made from a single strand? I wonder how long it is ......

Jim, K9JFK

  As mentioned earlier on this list server there exists a braided cord with stranded copper wire
braided within. The wires can be cut and removed from a point and on. This sounds perfect for
temporary, portable and emergency antennas that would need no end insulators. I would love to build
a complete set for every band with one feedline and balun making a dipole.
  (attached with a nut onto bolts on the balun, with sturdy eye lugs on the inner ends of the wires)

No, "tinsel wire" is telephone cord wire used in handset and pedestal cords.
I was referring to wire made to be used in constructing antennas. It is soft and limp, (like a thin
shoe lace) it was discussed here 3 or 4 weeks ago. I am planning on talking to Mr. Wireman at my
next big HAM-Fest to see what is available in the soft and light for temporary, portable and
emergency antennas that would need no end insulators.* I have a friend that bought 1,000 feet of
such wire from home and he built a 900 foot big loop around the treetops in his yard. Works fine
from DC to 6 meters.
* that can be kept in a sack or cloth shopping bag.

More hills in Washington state than in FL. We do emergency VHF with portable repeaters on the mountain tops where I live in CA. I have not had too much experience with 2 meters SSB. The less hops the better. I remember the old game we played in school on passing a phrase. When it got back to the beginning it was all wrong. NVIS is just perfect for 200 miles where hills are involved. I imagine in FL you can set up a nice 2 meter beam for SSB and talk from one end of the state to the other end.

Since I got my 857D I hardly ever use my VHF/UHF radios any more. When I can I'm going to get two 40 meter Sierra Slims and make myself a nice low dipole for NVIS.

Hello

I have a new MA5B and have an interesting problem. It calls for the boom "BB" to mount to the mast mounting plate with a 1 5/8 clamp.

BUT the diameter of the boom section itself is also 1 5/8 .

Thus no clearance to get the boom thru the clamps. I can not physically get it thru the clamps and don't really want to bend anything. Am I possibly misunderstanding these directions? ... any suggestions???

Thanks, Keith W9NFL

Topic: 19497 Message: 19497

While getting breakfast at the local Jack in the Crack today (Hey I love the new menu choices and often get 12 tacos ;), I saw a 20ft self supporting mast in front of their parking lot and it had a solid ball top and that caught my eye. I walked to it and sure enough, it looks like a portable 20ft antenna mast on a push in the ground mount....there was a sticker on it but there was a hose clamp blocking the name...the stupid crew inside came out telling me I cant look at it or take pictures!!! I showed them my Public Safety business card from the Sheriff's dept and they shut up!! I have the pics and can send them if anyone wants to see them (not sure if the list will pass them so I haven't bothered to xfer them yet)

Anyone else seen such at a JITB??? What the hell is it?? Cant support a flag of any decent size...and NONE of the crew knew what it was for!

I am sure there is no ground system under it...but I want one ;)

Hello Group,
I'm new to group and need information on an antenna that I have aquired. So let me describe it the best I can: It is factory made but without any labels or tags. The elements measure 275", 287", and 310". The 287" element is two pieces that the coax is hooked to. It has larger (13" X 1-1/8") @ 33" from each end on all elements. I'm marking the joints and taking them apart for cleaning. Should I use Noalox by Ideal or Pentrlox when puting the joints back together? It looks like there was some kind of joint compound on it before. I think it would be for 15 meters if I figured correctly. ???? Also if anyone has this antenna can it be turned with a TV type rotor? Thanks for any help.

19500. Re: [ham-antennas] 43' vertical antenna project questions

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-29 14:51:50 UTC
From: James Irving
Topic: 19456 Message: 19500

Hi Jay...

The ferrite used for common mode choke baluns is usually used in two forms. The first is a donut shaped ring and the coax is passed through the center 5 or ten times. However, if you are using anything bigger than rg59 coax, than passing it through the donut (toroid), can be a chore! The alternative is a "bead", which has a hole in it, and needs to be quite large to handle the big coax; however, you need to put anywhere from 5 to 10 beads on the coax. Your clamp on ferrite is a bead that is split down the middle so you can put it on after the connectors have been attached.

Amidion carries the beads and toroidal ferrite material... fb1020-31 beads are shown here...

https://www.amidoncorp.com/items/43

Some transmission lines are more flexible than others... you must check the specs for the minimum bending radius, then double that figure to get the circle diameter for putting it through a toroid. Remember, that is a minimum figure. The coax I'm using is very stiff, and in 1 or 2ft lengths can be hard to bend in a "small" diameter circle, and large diameter coax coils make the transmission line longer. Cost of the beads is offset by the savings in using less coax and the balun works better on a multi-band antenna. My vertical antenna is 140ft from the shack, so keeping it the transmission line as short as possible is a priority for me.

One other thing about a bead choke balun. You can cover it with electrical tape or with shrink tubing for a very neat installation... no coils to hide or look unsightly. I have no problems with winding a control cable around a donut shaped toroid. The cables are very flexible and you don't need a "big" toroid that handles a lot of power. You might want to try your clamp on choke on the control cable if you have any problems. I have an Icom AH4 remote tuner, but, as yet, have not had any problems with rf on the control cable.

Subject: RE: [ham-antennas] 43' vertical antenna project questions

I think I’ve seen that graphic, I guess the air wound is limited. I’m not sure what “8 beads of 31mix” actually means or what or were to buy them. I do have some clamp on style chokes, look like magnet material that I was going to put on the control cable.

I’m mounting the tuner in a plastic enclosure which has plenty of room and had thought about putting a MFJ-915 isolator http://www.mfjenterprises.com/Product.php?productid=MFJ-915 right at the tuner in the box with a short pigtail of RG58 or 8X. Do you think this suits that purpose ?

Subject: Re: [ham-antennas] 43' vertical antenna project questions

Hi Jay...

I used to think the air wound choke solution was adequate for keeping rf off the transmission line. After installing my antenna 150ft from the house, I wanted another solution.... found it here at the web pages of Steve, G3TXQ....

http://www.karinya.net/g3txq/chokes/

Look at the reactive impedance of the air chokes versus the resistive impedance of 43 or 31 mix ferrites. I am using 8 beads of 31mix over an rg213 sized coax. That doesn't mean I haven't, or wouldn't use an air wound choke; I just view it as a single band solution. Another reason I switched to ferrites was to reduce additional coax losses caused by increasing the length through air baluns.

I've got the beads at both ends of the transmission line even though it is buried in pvc conduit a foot down. After the installation, my first surprise was the vertical was "quiet". Don't know if that is because of the beads stopping rf shield pick-up or the buried coax, but its a "show stopper". Another ham a couple of miles away often comments on the noise p/u of his vertical and having to switch to his dipole. More often than not, my response is "What noise?"

BTW... Steve is well known for his work on the hexbeam and a tour of those pages makes for good reading....http://www.karinya.net/g3txq/hexbeam/

Subject: [ham-antennas] 43' vertical antenna project questions

I'm installing a DXE 43ft vertical with an Icom AH-4 tuner at the base.
Would it be a good idea to wind a choke right before the tuner ??

The coax the feeds back to the shack underground is RG213, would it mater if the connection from the antenna to the feed into the house is RG-8 or if I use a choke I make it from RG-8.

Don't have anymore RG213 and this project is replacing a Butternut vertical which used a peice of RG-11 as a matching section so the RG213 does not reach where the DXE will be.

Thanks Jay N1FDX

Since this is an antenna forum, thought I should let people know here first.
I'd like to sell my TH6DXX. I totally rebuilt it with new stainless hardware, trap end caps, etc. Cleaned out the bugs/spiders from traps when I took it totally apart before putting new parts on it. Also has the BN86 balun.
Obviously, this is a big antenna. Can certainly break it back down if that would make it shippable-I'm not sure just what size limits are as its been many years since I bought it. I'm in Buffalo NY area and willing to try and work something out.

I have a Mosley T-33 Jr 3 element beam, 10, 15, 20 meters. I don’t think a TV rotator will work. However I do think the TV rotator will drive my 17 M dipole. My antenna is Director 279 1/2”, Radiator 294 3/4”, Reflector 318 1/2”. My antenna is trapped. I do believe I have a HAM 4 rotator on mine. My setup is all hand me downs.

Subject: [ham-antennas] 3 ELEMENT YAGI

Hello Group,
I'm new to group and need information on an antenna that I have aquired. So let me describe it the best I can: It is factory made but without any labels or tags. The elements measure 275", 287", and 310". The 287" element is two pieces that the coax is hooked to. It has larger (13" X 1-1/8") @ 33" from each end on all elements. I'm marking the joints and taking them apart for cleaning. Should I use Noalox by Ideal or Pentrlox when puting the joints back together? It looks like there was some kind of joint compound on it before. I think it would be for 15 meters if I figured correctly. ???? Also if anyone has this antenna can it be turned with a TV type rotor? Thanks for any help.

I ran a TH3JR for years with an Archer Rotor.. I had to change gears out only once as they were teflon.

But ran over 15 years like that.

I wish you would have included a price . It is all for naught regardless for I am in Texas . I have owned the TH6DXX and a TH7DXX and have the manuals for each as well as the Hy Gain comparison charts . I find myself in the market for another but doubt a drive to Buffalo in my near future . Subject: [ham-antennas] TH6DXX for sale

Since this is an antenna forum, thought I should let people know here first.
I'd like to sell my TH6DXX. I totally rebuilt it with new stainless hardware, trap end caps, etc. Cleaned out the bugs/spiders from traps when I took it totally apart before putting new parts on it. Also has the BN86 balun.
Obviously, this is a big antenna. Can certainly break it back down if that would make it shippable-I'm not sure just what size limits are as its been many years since I bought it. I'm in Buffalo NY area and willing to try and work something out.

I has the big brother of that antenn the TA-33 KW or more version.
On an old U-110 rotor. All metal drive train and final out put was a
worm gear drive so semi locking without a brake.

And I never had it move in a wind storm.

It worked easily over a decade. the only trouble it ever gave me was if
it was very windy it would tend to stall out when trying to move.

but otherwise for a 10 dollar garage sale rotor vs a 400 or more one
i'll take the ten buck one anyday.

Hi All

I found that the Bencher website has some really interesting files and I have asked permission to put them in the groups files section, I have been granted permission (I can forward confirmation to moderator if required) but the following must be noted:-

Each file posted must be complete, not shortened or edited in any
way. (done)

Each file must start with the comment that the file is the
copyrighted property of Bencher, Inc. and is posted with
permission, and is not to be posted elsewhere without the express
permission of Bencher, Inc.

Each file must include the URL for the Bencher site. (I do not have PDF editor program so please note this and if possible go to http://www.bencher.com)
I will do a readme file with a copy of these conditions and Bencher's website address.

I would like to thank Bencher for granting permission and for their quick response to my enquiry.

Jon

If you only have two traps per element (one on each side) you may have a Mosley , check out http://www.kc5wa.net/ta33/ta33.html , for pictures and run down Mosley info, TA 33 and/or TA 33jr. Cushcraft , Wilson and others used two traps per side , 4 per element.

Its like a pop bottle thingy near the end of the elements, there are more than one type can be coils of wire,used to shorten the antenna
I don't have the literary skills
 to put down in words what I am thinking,
maybe some one else can describe a trap better than I can.

Hi Jo...

I've been using the free home version of PDF Exchange Viewer from Tracker Software for several years.....
http://www.tracker-software.com/product/pdf-xchange-viewer

It allows you to make annotations into a pdf file, plus some other things, ... nice features and reliable.
If you couple this with the free Primo Pdf, which installs as a printer option.....

http://www.primopdf.com/index.aspx

you'll have a dynamite pdf combo. Anything you can print, including web pages, can be turned to a pdf. That includes any ".doc" files you want to attach to emails; I don't usually open ".doc" email attachments because they can contain virus macros. That is not a problem if converted to pdf before attachment.

If the aluminum tubing was a snake the "trap" is the rabbit in the middle of the snake, swollen up.

Thanks Jim for the info below. I’m real close to getting it on the air, I think by this weekend. I guess I don’t really know if I have a problem, just trying to stay ahead. The Butternut did on some bands. The MFJ-915 I mentioned below sounds like a readymade solution to what your explaining. I am using RG213 to the antenna and made a pigtail out of the AH4 which I can either add the rings to or try the MFJ while waiting for an order. Also I guess would give me the option to see if I need anything. This connection will be out of the weather inside a 12x12 enclosure with the AH4.

Subject: Re: [ham-antennas] 43' vertical antenna project questions

Hi Jay...

The ferrite used for common mode choke baluns is usually used in two forms. The first is a donut shaped ring and the coax is passed through the center 5 or ten times. However, if you are using anything bigger than rg59 coax, than passing it through the donut (toroid), can be a chore! The alternative is a "bead", which has a hole in it, and needs to be quite large to handle the big coax; however, you need to put anywhere from 5 to 10 beads on the coax. Your clamp on ferrite is a bead that is split down the middle so you can put it on after the connectors have been attached.

Amidion carries the beads and toroidal ferrite material... fb1020-31 beads are shown here...

https://www.amidoncorp.com/items/43

Some transmission lines are more flexible than others... you must check the specs for the minimum bending radius, then double that figure to get the circle diameter for putting it through a toroid. Remember, that is a minimum figure. The coax I'm using is very stiff, and in 1 or 2ft lengths can be hard to bend in a "small" diameter circle, and large diameter coax coils make the transmission line longer. Cost of the beads is offset by the savings in using less coax and the balun works better on a multi-band antenna. My vertical antenna is 140ft from the shack, so keeping it the transmission line as short as possible is a priority for me.

One other thing about a bead choke balun. You can cover it with electrical tape or with shrink tubing for a very neat installation... no coils to hide or look unsightly. I have no problems with winding a control cable around a donut shaped toroid. The cables are very flexible and you don't need a "big" toroid that handles a lot of power. You might want to try your clamp on choke on the control cable if you have any problems. I have an Icom AH4 remote tuner, but, as yet, have not had any problems with rf on the control cable.

Subject: RE: [ham-antennas] 43' vertical antenna project questions

I think I've seen that graphic, I guess the air wound is limited. I'm not sure what "8 beads of 31mix" actually means or what or were to buy them. I do have some clamp on style chokes, look like magnet material that I was going to put on the control cable.

I'm mounting the tuner in a plastic enclosure which has plenty of room and had thought about putting a MFJ-915 isolator http://www.mfjenterprises.com/Product.php?productid=MFJ-915 right at the tuner in the box with a short pigtail of RG58 or 8X. Do you think this suits that purpose ?

Subject: Re: [ham-antennas] 43' vertical antenna project questions

Hi Jay...

I used to think the air wound choke solution was adequate for keeping rf off the transmission line. After installing my antenna 150ft from the house, I wanted another solution.... found it here at the web pages of Steve, G3TXQ....

http://www.karinya.net/g3txq/chokes/

Look at the reactive impedance of the air chokes versus the resistive impedance of 43 or 31 mix ferrites. I am using 8 beads of 31mix over an rg213 sized coax. That doesn't mean I haven't, or wouldn't use an air wound choke; I just view it as a single band solution. Another reason I switched to ferrites was to reduce additional coax losses caused by increasing the length through air baluns.

I've got the beads at both ends of the transmission line even though it is buried in pvc conduit a foot down. After the installation, my first surprise was the vertical was "quiet". Don't know if that is because of the beads stopping rf shield pick-up or the buried coax, but its a "show stopper". Another ham a couple of miles away often comments on the noise p/u of his vertical and having to switch to his dipole. More often than not, my response is "What noise?"

BTW... Steve is well known for his work on the hexbeam and a tour of those pages makes for good reading....http://www.karinya.net/g3txq/hexbeam/

Subject: [ham-antennas] 43' vertical antenna project questions

I'm installing a DXE 43ft vertical with an Icom AH-4 tuner at the base.
Would it be a good idea to wind a choke right before the tuner ??

The coax the feeds back to the shack underground is RG213, would it mater if the connection from the antenna to the feed into the house is RG-8 or if I use a choke I make it from RG-8.

Don't have anymore RG213 and this project is replacing a Butternut vertical which used a peice of RG-11 as a matching section so the RG213 does not reach where the DXE will be.

Thanks Jay N1FDX

Harold Sir,
I made my own version of 43 footer ground mounted vertical and with great success I found the secret was I laid down 2000 feet of counterpoise to cover my back yard, I used from 8 feet lengths to 67 feet in lengths this has worked very well for me.
good luck and have fun
best of 73

My antennas are down courtesy Irene. No great hardship, though. I will out the verticals back up in about 30 minutes. My 80m dipole is a mess, though. I have a G5RV Junior that I may use in it's place.
Here's the question: I'm thinking of attaching the 80m elements to the G5 RV Jr.
Bad idea? Anybody ever try anything like this before?

Looking forward to any and all input. Thanx all in advance. Mike

I checked the pictures on www.kc5wa.net sight and my antenna is exactly like the pics. This antenna was @ an estate on a 70' tower. I took it down and am in process of putting it back in use after years of not being used. how can one test the traps to be sure they are good. Are they coils that can be ohmed out? can they be took off and checked out? What do I need to do to check them before going back up with it? Also when cleaning the tubing joints can I use a joint compound like Noalox or Pentrolox when putting them back together? Thanks for all your input.

You answered you own questions. You need to disassemble the entire antenna one joint at a time.
Several saw horses or such will bring it up to nearly waste level, always nice.
Record ALL measurements before starting. Mark with a felt tipped marker as you wish.
Never use steel wool, use "scotch bright" type of abrasive plastic pads* to brighten (and remove
all aluminum oxide - white dust) all contacting surfaces and apply a thin film of your favorite
"Anti-Ox" compound to all polished surfaces. The "traps" contain one or more coils and one or more
capacitors (I do not know your unit) and they are usually wound with aluminum wire and all
contacting surfaces need to be cleaned and de-burred before re-assembling. (file if required)
A very close visual inspection (and Ohm it out) is important to minimize having to take it back down
to replace them. They usually can be tested with a GDO Grid Dip Oscillator. I do not know what
frequency they should resonate at.
BTW: Replace any questionable hardware and when you are done have no non-stainless steel "up
there." Be especially careful of the little sheet metal screws in and around the traps.
Remember any hole (no mater how small) drilled in aluminum tubing weakens it, if it isn't
necessary (sometimes it is) don't drill.
With luck the antenna will not need to be lowered for 10 or 20 years, barring lightning damage,
traps can be damaged by lightning and other things. Plastic caps on the ends of the traps should be
replaced if they do not look new.

Another trick is to have a six to ten foot "whip" cable between the beam and the tower (the part
that coils up and uncoils when the rotator is rotated) and tie the cable coming up the

tower to the
tower with an hose band so it can't move. Replace the "whip cable" every few years depending on
weather and the number of times the antenna is rotated.

In many areas there are "riggers" (tower workers) that give deep beaks to HAMS, to do it safely.

Larry,

Which end of a G5RV is "the short end"? I thought a G5RV had two 51-ft wires.

It will leave minute steel spears stuck in the aluminum, when they rusts they can create a diode
like structure* and if in sufficient quantity, an electrical insulation layer.

Ok so it's all about surface scratches, so using like 0000 steel wool
would make a like mirror finish would be fine,
Other than that possible stray wire.

No, it's nor the finish it's that you are, unbeknownst to you, adding a layer of micro fine iron
particles between two layers of aluminum. read: Dissimilar metals! It doesn't mater how many "0"s
there are on the package, it happens. Thousands of microscopic spears.

My friend Sigi is right as usual. When making fatigue test specimens to meet FAA specifications the requirement was to use carbide scrapers, new, not re-sharpened files and new emery sheets to deburr alum billets that were being machined for material certification. It might be a overkill for what we do but it can't hurt to try to be right.

Only if the steel wool is of a course nature.... can be purchased in several grades, with the finest able to remove minor imperfections on a finished wood surface, without damage. However, the steel can embed itself as minor particles in the aluminum surface, and it will eventually rust. Now you have a really bad looking aluminum antenna!

Yes, the Scotch pads are good for aluminum, and they also come in several grades. Personally, I use 120 grit plastic "grids" that are sold to finish plaster and drywall... lasts a long time and are inexpensive. They do not "block" because of the grid structure; sheen can be imparted with a Scotch pad when the main cleanup is done.

HI all,

I agree after20 years selling abrasives the comments below carry an element of truth.

I would scribe mark the elements where they are set and also the boom where the elements cross, then strip and clean I element at a time and replace. Be aware that this however careful your are may alter the tune of the YAGI and it will have to be re-tuned!!!

Aluminum oxidizes as soon as the new metal is exposed to the air , also ensure your anti-oxidant is compatible to the Aluminum do not use a copper or nickle based products or you will set up an electrolytic condition/situation.

Jeff

Ok so it's all about surface scratches, so using like 0000 steel wool
would make a like mirror finish would be fine,
Other than that possible stray wire.

No, it's nor the finish it's that you are, unbeknownst to you, adding a layer of micro fine iron
particles between two layers of aluminum. read: Dissimilar metals! It doesn't mater how many "0"s
there are on the package, it happens. Thousands of microscopic spears.

19532. Re: [ham-antennas] Comments, please?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-31 00:18:29 UTC
From: Larry Tooley
Topic: 19519 Message: 19532

Hit me with a board, Frank!

Sorry I and a bunch of my repeater buddies have been miscalling the Off Center Fed (OCF) antenna, a Windom or G5RV antenna. Thanks for catching this so we will learn that the G5RV is a great different antenna.

My OCF antenna is cut for 80-6 meters-45' one side and 90' on the other. I don't see why I cant add 135' to the short side to get the 180' for 160 meters.
This is borrowing the Buckmaster data from:
http://hamcall.net/7bandocf.html

The Windom: http://www.g4nsj.co.uk/windom.shtml

Larry,

Which end of a G5RV is "the short end"? I thought a G5RV had two 51-ft wires.

From: urei
Topic: 19519 Message: 19533

Glad we got that straightened out. THe original question remains.
For clarification, mine is a G5RV JUNIOR. Center fed, not OCF. I believe the overall length is 51' and the window line is something like 16'. My question is: has anybody added two 60' wires to a G5RV Jr? What results? Better to add the 60's in place of the 26's or set it up like a fan dipole with the windowline connected to the 80m elements AND the G5RV elements? Thanks. Mike

Just out of curiosity, where are you thinking about adding those 60' wires? At the feed point in parallel with the G5RV, perhaps on another axis? Or as extensions on the ends?

Andy

19535. Re: Comments, please?

Yahoo group: ham-antennas (2011-08 — 2011-12)

Topic: 19519 Message: 19535

In answer to your question, Andy, I'm thinking of attaching the 60' wires either in parallel to the short elements or in place of them. The wires would, in either case, be attached to the top of the window line.
So far I'm most curious about adding them in parallel to the 26' elements like a fan dipole. Hope I'm clear. If not let me know and I'll try to clarify. Thanks for your input.

19539. RE: [ham-antennas] Re: 20ft pole found at Jack in the Box

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-31 13:38:33 UTC
From: Gary H. Harmon, Jr.
Topic: 19497 Message: 19539

But, let's look at the reality of the situation. If you have a list with 6,000 members, you wouldn't want to send a 1MB file to all 6,000 members. Probably, 5,990 would scream and 10 would be happy. By posting the attachment to the FILES area, anyone can look at it without flooding the internet with data.

Thanks for everyones input, This is the BEST informational group that I have joined. I can get underway rebuilding the antenna and maybe get in the air waves soon. Thanks again. Nate

So now that you have your answers on the antenna what are you mounting it on and how high up. Just curious.

From: AlainMichel
Topic: 19498 Message: 19542

Nate,

I have a 5 element Yagi for 220 MHz that was given to me in poor shape. I wire brushed it and then spray painted it with a Rust-oleum product called, "MultiColor Textured". It is a non-metallic spray that works very well.

I live in a CC&R area so I chose a color that would help blend the antenna into the surrounding trees and hills.

The antenna has been up for 4 years now. Works great, no breakdown anywhere and the SWR still remains a comfortable 1:2:1.

Hope this helps.

Alain

19543. Loop antennas?

I'm buying myself one of these little MFJ loop tuners because I'm curious about loops antennas.

How do loop antennas compare to dipoles for QRP DX?

Are the tales of being able to run a loop at earth level true or just myth?

73s geo VE3GZB

Hi geo
Don't buy make it!!! absolute doddle 10mm or 3/8" copper pipe and an old variable capacitor out of valve era radio. Now they are not pile up busting (in my case anyway) but they work. I have use mine in upstairs bedroom of our house on 40m and got DL station.
have fun

Well, it's already bought and being shipped. I might run 120W on it or I might run QRP, so I wanted the voltage ratings.

But what I wanted to know was how it compares to a dipole for QRP DX? Does a loop need to be at a certain height to work, like a dipole?

What are the pros and cons?

Thanks and 73s geo VE3GZB

That's ok - my short dipole doesn't rotate and I use it on 20 and 17m.

For example, I have worked from my QTH (1.5 hours NW of Toronto, Ontario) to Idaho on 5 watts PEP and recently California on 10 watts PEP.

Can a loop give me comparable performance?

This isn't a normal sized loop. It's one of those compact loops that
can sit in your room or balcony.

I think there can be a big difference in performance between the two.
But I'm no expert.

Andy

Oops
Right here goes my take on it. they are inherently high Q devices with very narrow bandwidth so if changing frequency up or down more than a few Khz need adjustment of capacitor, being high Q they can develop high voltages across the open ends where the capacitor is fitted, we are talking several KV so ideal for QRP but not I would recommend 120W I only ran 10W.
I don't know if it applies in VE land but I seem to remember that US stations have to do some sort of RF risk assessment nowadays and I am not sure about distances required to away from antenna for various power levels. This may be something you might want to look into.

Sorry not really answering question but general rule with antennas is higher the better and next to sea water better still.

still learning this end

I wold have to think any dipole that is mounted outdoors in the air a decent height is going to out perform the small loop.

I am going to build a single band loop, have the plans here somewhere that allows it to be built without the capacitor.

Mine will be mounted out doors somewhere.

Jon hit on a major point of it being very narrow in bandwidth in comparison to a dipole.
A point to think about when you have a small dia loop tuned to a frequency like 20M it covers only small amount of space and thus receives only a limited amount of electrical energy , with a 1/2WL dipole more space is covered so a lot more energy will be received and thus a better received and sent signal strength. Just as my large loop has gain over a 1/2WL dipole, so remember , size does matter in some things.
Rich , KDØZZ , ☺

I know that you believe that you understood what you think I said, but I am not sure you realize that what you heard is not what I meant

Rick,
Please share your small loop ,no capacitor plans when you find them.
Thanks
73 Ken..... k5jxl@...

Subject: [ham-antennas] Re: Loop antennas?

I wold have to think any dipole that is mounted outdoors in the air a decent height is going to out perform the small loop.

I am going to build a single band loop, have the plans here somewhere that allows it to be built without the capacitor.

Mine will be mounted out doors somewhere.

I have one of the MFJ 9-33 MHz units and I think it performs just as good as a dipole, but the
pattern is different. It is rated at 200 Watts. (mode unknown)

Topic: 19498 Message: 19556

I'm seeing much discussion of 3-element yagis and other types for 10 meters. For years I used a Sommer XP-807 Multiband Beam on top of an 18 meter high tower and it was wonderful. However I got out of ham radio for about ten years and just recently decided to get back in! (seems we might be approaching a time when we need emergency communications, hi) I just finished constructing a couple weeks ago a simple, cheap, 3-element wideband, short-boom yagi especially for 10 meters, and the unique thing about is it has one director and dual-driven elements and no reflector. I've already over 20 countries with it PSK31 and PSK125 modes! I have a link to the simple design of it in the second paragraph of my personal web page here: http://www.cdagro.com/CD5846/CD5846.html and if I can build it, anyone can! I used a strange combination of tubes--the center driven element is 1/2 inch copper tubes, and the director and rear driven elements are from 7/8" diameter aluminum tubes, and the short boom I cut from an old piece of 2" aluminum irrigation tube that I happened to have! I'll be happy to email photos of the antenna to anyone interested. My email at www.qrz.com .

There are some plans for a loop without the variable capacitor and it uses a section of coax as a capacitor but it cannot change frequency.

19560. Coax to 20 meter dipole question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-08-31 21:22:08 UTC
From: neilkj6fba
Topic: 19560 Message: 19560

I am upgrading my ticket to general in two weeks (assuming I pass!). I will be erecting a 20 meter band dipole for a new HF transceiver and I have access to a large quantity of RG6 quad shield coax. It is, of course 72 ohm and the ideal would be 50 ohm. The coax run will be about 50-65 feet. Is this going to be a significant problem if I use this quality RG6 ?

Comments will be most welcome!

Neil Bell

From: Larry Tooley
Topic: 19560 Message: 19561

Oh yes! Ship it all to me. Just kidding.

Between two trees 40 feet up giving you 50 ohms. Your 75 ohm coax I think will give you a 1:5 to one SWR.

I love my large loop. If I was ever to build a small loop antenna I would copy N3KNZ's http://www.standpipe.com/w2bri/article7.htm

Octagon loop on the lower part of the page, this starts to go beyond antenna work and into art work. This could go on a porch and who could complain.

It will work fine. A antenna is sometimes closer to 70 ohm then 50, it all depends on what is near it and how high or low it is.

Topic: 19543 Message: 19566

Not to add any controversy to the discussion but I have a vertical loop I use on 80/ 75 meters and I have worked 75 countries over the past 2 years. It's 60 feet tall on each vertical leg and 100' across on the horizontal legs. I feed it at the bottom horizontal leg center point with 450 ohm twin lead and an antenna tuner. I do have to re-tune via the antenna tuner if I move from one end of the band to the other, but as far as 25khz or so, no sweat, no need to retune.

I have used horizontal loops successfully before, same configuration only horizontally polarized instead of vertically. I found this to be nothng more than a cloud burner. Maybe 500 - 1000 miles. Could hear the dx, but contacting them was next to impossible.

Thanks for the bandwidth.

Dave

Subject: RE: [ham-antennas] Re: Loop antennas?

Jon hit on a major point of it being very narrow in bandwidth in comparison to a dipole.
A point to think about when you have a small dia loop tuned to a frequency like 20M it covers only small amount of space and thus receives only a limited amount of electrical energy , with a 1/2WL dipole more space is covered so a lot more energy will be received and thus a better received and sent signal strength. Just as my large loop has gain over a 1/2WL dipole, so remember , size does matter in some things.
Rich , KDØZZ , ☺

I know that you believe that you understood what you think I said, but I am not sure you realize that what you heard is not what I meant

Subject: RE: [ham-antennas] Re: Loop antennas?

Oops
Right here goes my take on it. they are inherently high Q devices with very narrow bandwidth so if changing frequency up or down more than a few Khz need adjustment of capacitor, being high Q they can develop high voltages across the open ends where the capacitor is fitted, we are talking several KV so ideal for QRP but not I would recommend 120W I only ran 10W.
I don't know if it applies in VE land but I seem to remember that US stations have to do some sort of RF risk assessment nowadays and I am not sure about distances required to away from antenna for various power levels. This may be something you might want to look into.

Sorry not really answering question but general rule with antennas is higher the better and next to sea water better still.

Since dipoles are 73 Ohm devices that should work perfectly.

It's the nature of dipoles to be resonant at the design (formula) frequency with a 73 Ohm load at
it's center with little reactance. (or with an unbroken center)

Loop, LOOP, loop, lets keep "big loops" (such as this) separate from the small "magnetic loops"
that are "resonated on frequency" in our minds.
The horizontal big loops tend to produce a primarily horizontally polarized signals and the vertically orientated big loops tend to produce a primarily vertically polarized signals, which for
several reasons work better for DX. (A dipole antenna's signal after one bounce tends to arrive
vertically polarized)

True if it's in free space. Above earth, and near buildings and other objects, it will be different.

Bottom line is, it's not going to make a big difference to this antenna. It'll work. Could it be better with another coax? Probably. Would you notice the difference? Not necessarily.

Some cases to consider: If the dipole happens to come out at 75 ohms, then the SWR on the coax is ideal (1:1), and your rig would see a 1.5:1 SWR looking into it. If the dipole is at a height that makes it around 50 ohms, then the SWR on the coax is 1.5:1, but the SWR seen by your rig could be anywhere from 1:1 to 2:1 depending on coax length. If it's a quarter wavelength long (or an odd multiple), it would transform 50 ohms at one end to 100 ohms at the other. Neither of these is really bad; but you might be a tad better off using 50 ohm coax because the SWR relative to 50 ohms stays a little lower. That's not enough reason to throw away a bunch of RG-6 you already have, I think.

Andy

Hi Group,

Yes big loops work entirely differently to small loops. It's because small loops interact far more with the H-field (magnetic) and the large ones more with the E-field (electric).

BTW there is a dedicated Yahoo group for small loops.

Small loops do not give something for nothing. Looking at the professional research on small antennas, they have a worse Chu limit than their electrically based cousins.

Going back to the original question, a small loop will not compare to an outdoor dipole for QRP DX. But it will get you on the air, you just have to wait a bit longer for a break in conditions.

73s,
Rob.

Neil

Today's transmitter want only a 50 ohm load on any band, using a complete run of 75 ohm coax is not a good idea it will give a 75 ohm load at the transmitter use an antenna analyzer before going on the air at the transmitter end to find out what the transmitter is seeing as a load,you can also profile over the whole frequency range of operation.

Suggest you test the installation before finalizing things leaving the coax and antenna easily accessible,have you comfier the coaxial balun etc you also need or the 1:1 balun remember your going from an unbalanced to balanced situation.

Has your general class ticket covered of the aspects or do you need to do more study?.

One of the locals has now got his transmitter limiting to 65 watts due to the self protection circuit operating due to an antenna that out of range.

That is why older tube rigs had a matching and loading operation to match transmitter to the antenna. Your modern antenna tuner on modern rigs is doing the same thing there is a limited range of adjustment though refer to your spec sheet.

I used a 75 ohm matching section to lower the impedance from 100 ohm to 50 ohms and the length was only 1/4 wave matching section. Calculate what wavelength 65 feet gives you on 14 mhz band.

Suggest you look at a ARRL handbook and look up antenna matching and antennas sections.
ARRL's Small Antennas for Small Spaces
Find the right antenna design to fit your available space. Includes ideas and projects to get you on the air regardless of where you live!

The ARRL Antenna Compendium Volume 8
Proven HF and VHF designs from the pages of QST.

On a beam antenna that is why you have a matching device at the driven element to give you a match close to 50 ohms

ARRL also makes antenna only reference a dipole is just one antenna design I used a loop antenna for 20 meters and out preformed other wire antenna designs on a city lot and was only 5 feet off the ground at the bottom.

Even though a higher dipole(had a 40 foot advantage based on the apartment building height) had less success, my lower mounted antenna made the contact on first call. height is not always the deterring factor. The loop antenna was a very simple factor for a 25 foot tower support structure.

An old adage the antenna makes or breaks the installation.

Consider all your options after doing some research.

Good Luck

I'm using a TS-830S and it's transmitter output ratings are: 50-75 Ohms (read from the users manual).

My guess is that other transceivers might or might not be as flexible. Maybe tube/hybrid transceivers are more flexible?

But always please read your users manual to confirm or deny your transceiver's output requirements.

Well I’m using an old FT-950. I bought it in 2007, Hi Hi. The Antenna Impedance is 50 Ohms unbalanced and it also says 16.7 – 150 Ohms unbalanced (Tuner ON, 160 – 6 m Amateur bands, TX only).

So I’m taking it that my radio will work with an Antenna Impedance of 16.7 – 150 Ohms unbalanced. Right at the top of my feedline to the antenna I have an “Ugly Balun” so my feedline is not part of the antenna and it keeps the RF out of my shack.

19578. OCF Antenna Question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-02 15:04:34 UTC
From: AnthonyS
Topic: 15544 Message: 19578

I have come across at least 5 manufacturers of OCF dipoles for 40-20-10-6 Meters. They all have the same dimensions, namely 23 ft on one side and 45 ft on the other of the center OC feed point. Some use 6:1 baluns some use 4:1 baluns.

My question is...are they all really the same OR is there possibly a difference in design and performance. They all claim to be the best OCF dipole. Over the last three years I have used (for various reasons) two different ones and about to try a third. I have see differences but not sure if it is due to propagation or the actual antenna.

Any thoughts?

Tony
WA2LNC

19579. Re: [ham-antennas] OCF Antenna Question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-02 15:43:21 UTC
From: Frank Kirschner
Topic: 15544 Message: 19579

I haven't tried them all, but it seems to me that if the dimensions are the same, the only difference would be the quality of the materials and workmanship. Unless one uses a toroid with high loss, the on-air performance should be the same, unless one winds up lying on the ground due to poor quality materials or workmanship.

19580. RE: OCFD QUESTION

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-02 16:12:06 UTC
From: John Gatwood
Topic: 19580 Message: 19580

Given that ALL dimensions AND feeds are the same (to include wire gauge of the dipole segments) the antennas in question SHOULD preform in a near identical manner.

Having said that (and most likely stuck my foot in my mouth) , the next thing to look at is , of the group in question are they ALL true OCFD's ? , COAX feed to the balun / center insulator ? , or is there ladder line / window line involved and what length (this would bring the antenna closer to the original "WINDOM" configuration).
Wire diameter / type of the Dipole is also a big factor, the conductivity factor of copper is less than copper clad steel or stainless steel.

There is quite a bit of information on the net about OCFD's and "WINDOM's" , you have to decide which is right for you .

Date: 2011-09-02 17:05:19 UTC
From: jo barden
Topic: 15544 Message: 19581

Hi Tony

I use an OCFD and can attest that it at my QTH is a good antenna, for info go to http://hamwaves.com/cl-ocfd/principle.html now to address some of your points as I understand it with the offset the impedance should be of the order of 300 ohms however that is with the antenna being up at a reasonable height (in wavelengths) so when closer to the ground the impedance will be lower. Also making 6:1 balun involves effectively making 2 baluns whereas for 200 ohm a single 4:1 balun can be used which is easier to make.

I use a Z11 pro11 tuner with mine and I am happy with this setup. My views on tuners has changed over the years and now I just accept it as part of a multi-band system. Yes you might have SWR of 1:1.5 on some bands but I have a great big Oak tree in next doors garden overhanging my antenna so I need a tuner.

The antenna is easy to make and even the balun is not hard. My balun is made with torrid but I have just won some old AM radio ferrite rods so I am going to be making one using two of these. I only run 100W so flux saturation should not be a problem but I like "playing"

Have fun and if you want plans I can email them to you.

Subject: [ham-antennas] OCF Antenna Question

I have come across at least 5 manufacturers of OCF dipoles for 40-20-10-6 Meters. They all have the same dimensions, namely 23 ft on one side and 45 ft on the other of the center OC feed point. Some use 6:1 baluns some use 4:1 baluns.

My question is...are they all really the same OR is there possibly a difference in design and performance. They all claim to be the best OCF dipole. Over the last three years I have used (for various reasons) two different ones and about to try a third. I have see differences but not sure if it is due to propagation or the actual antenna.

Any thoughts?

Tony

Actually, you can make a 6:1 balun with a single core easily. You just need a turns ratio of the square root of six, or around 2.4. So 12 turns in the secondary to five turns in the primary would give you a 6:1 impedance ratio.

Hi Tony,

See here:
http://hamwaves.com/cl-ocfd/offset.html

It's possible to use different feedpoints on OCFs. Which is "best" depends on what bands you want to cover, and what SWR you expect.

Aside from feedpoint, the main difference between OCFs is those with a current balun or those with voltage balun. The latter use the coax as part of the antenna.

73s,
Rob.

From what I understand is the Carolina Windom is far superior to most manufacturers OCF dipoles, of course you need room and have to keep it flat.

Tony,

The quality of the balun is the major cost driver and, of course, wire quality can also impact cost. The balun design/construction can have a impact on performance characteristics and the long term reliability of the antenna.

I built my own OCF cut for 80m and it has low SWR on 80-40-20-17-12-10-6, but worthless on 15m. SWR is under 2.2:1 everywhere on those bands - actually under 1.5:1 most places I operate, but I normally use a tuner anyway. My dual (4:1 impedance and 1:1 current since the OCF will tend to send RF back to the shack) balun was about $100 since I did not build it and I run up to 800W through it so bought a 2kW rated balun.

You can do a little research, but I've seen 4:1 recommended for installations less than 40' high and 6:1 for higher than 40' in order to properly match a 50 ohm feedline to the antenna impedance. Mine is pretty much flat top now at about 28', but I plan to raise the center another 5' or so.

The only way I know of checking them is to have, some very expensive test equipment in a anechoic chamber or put two or three up at the same time , same height, same direction same feed length and a coax switch. To say you had a 57 report on Tuesday and a 59 on Friday is apples to oranges.

Jon, G6UWK you are correct about a 6:1 balun.

I have made 1:1, 2:1, 4:1 and 9:1 baluns but never a 6:1 so not knowing how I got out my book by Jerry Sevick, W2FMI and he has schematics on both series and parallel type baluns and both use a 1.56:1 unun into a 4:1 balun to come close to a 6:1 setup. None of his are on a single core.

Reference: Understanding, Building and Using Baluns and Ununs, by Jerry Sevick

Rich ,Kd0zz

My version is 22' + 44' fed via a 4:1 current balun. which gives a good match on 30/14/28/50 Mhz & Atu for 60/40/18/21.

its fed with 50 coax.

Another one I HAVNT tried but appears to give a better match has thev legs @ 14'+ 54' again fed via a 4:1 CURRENT balun.

John,
 Were you saying that copper clad steel and stainless steel were worse conductors than copper? About the only thing better than copper is silver. Stainless is a very very poor conductor for an antenna.

Given that ALL dimensions AND feeds are the same (to include wire gauge of the dipole segments) the antennas in question SHOULD preform in a near identical manner.

Having said that (and most likely stuck my foot in my mouth) , the next thing to look at is , of the group in question are they ALL true OCFD's ? , COAX feed to the balun / center insulator ? , or is there ladder line / window line involved and what length (this would bring the antenna closer to the original "WINDOM" configuration).
Wire diameter / type of the Dipole is also a big factor, the conductivity factor of copper is less than copper clad steel or stainless steel.

There is quite a bit of information on the net about OCFD's and "WINDOM's" , you have to decide which is right for you .

Hello Tom:
Actually I think this wound up in the wrong place, I was trying to answer another thread.
But to answer your question, yes the conductivity of CC steel is slightly less than copper , I have worked in power production for the last 25 years and have had occasion to play (test) with many types and compositions of conductors .
I have made dipoles using stainless and they do work to fair effect, you just have to allow for the conductivity of the wire.

I am curious. I have always heard that RF traveled on the skin. If that is so what would the difference be with copperweld VS copper. The copper is comparatively thick on copperweld. At 60 cycle or DC I could see a difference but not at 14Mhz.

RF does travel on the skin , as does A.C. and D.C. .
The physical size of the conductor (and / or the composition) is to satisfy strength and heat dissipation.

Rf does travel on the skin ... right ... but ac and dc???
That is new to me ...
I ever thought the wire dimension is calculated to give the ampere per square mm (for dc and lower ac) and not for giving the skin surface for xy amperes
I learned electrician and so I will have to give my money back ... all I learned seems to be wrong :-)

19596. Re: OCFD QUESTION

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-03 11:11:50 UTC
From: w9wls
Topic: 19580 Message: 19596

Some years ago the company I worked for bought some "SEMANS/Westinghouse" medium voltage (480 Volt +) switch-gear, the interesting thing about this gear was that instead of the usual thick heavy copper-alloy buss bars we found that the manufacture had used plated tubing and the "bucket" contacts appeared to be not much more than pieces of #8 wire which straddled the tubing when the bucket was in place.
This gear was used in several motor control centers (both A.C. & D.C.) with no problems for many years, we on the field engineering side were to say the least Leary of the stuff especially when starting several 100 amp or better motors, but after doing thermal imagery studies on it and comparing to other "SOLID BUSS" gear with similar load's we found that there was actually less heat build up with the "TUBE & PIN" gear.
The only real fault we could find with the gear was that the "BUCKETS" were constructed with rather thin sheet metal stock which allowed them to twist and bind if removed and re-seated which made us have to remove the back covers to verify that the contacts were properly seated (a practice not allowed on a live buss today).
The above certainly re-arranged my thinking about current flow and handling..... THINK ABOUT IT !

From: jo barden
Topic: 19580 Message: 19597

I must admit when I was on the Railway 25KV AC busbars were tube but 1500V DC 1KA were solid, if I remember correct from my apprenticeship HV and RF mainly conduct via skin effect but where the actual transition is I do not know. The 25KV busbars were only carrying about 200A so not high current but it was about 13/4" - 2" diameter and flattened at connection points for bolting to components (Pantograph, Circuit Breaker HT cable) but the bolts were normal steel. On the 1500V stuff the connections were with copper threaded and some copper nuts but not always.

I know what you mean though about whats not allowed now, we used to check rectifier trays (1500V) using tong tester on rectifier connections all open and the apprentice applying power against the brakes or looking for current imbalance by shutting off power and seeing which contactor drew the biggest arc.

Perhaps those days are best forgotten about!

Nothing to do with skin effect which occurs at higher frequencies due to inductive reactance peaking at the conductor centre, in this case negligible at DC or 50-60hz AC, and more to do with the more effective heat dissipation area of the tubular conductor, hence a lower operating temperature.

Adrian vk4tux (A class Electrician)

Absolutely correct. The higher the frequency the less current travels in the center.
The necessity to use copper for antennas has been over emphasized in many of these lists.
Huge commercial antennas such as "Sterba curtains" have been constructed with non-copper conductors
such as zinc coated steel and phosphor bronze frequently 1/2 to 1" in diameter and feed with 50 kW
and up. (shortwave stations)
Most commercial 2 meter (and up) mobile antennas (with possibly the only exception being the
Larsen cool-rod - copper then nickle plated SS) are made from stainless steel and although replacing
them with a copper wire might get an additional block of distance, driving at 70 MPH would bend it
back parallel with the roof of the car.
If it were so important to use "only pure copper" Motorola, all others and the military would use
copper coated phosphor bronze (or whatever) but they don't. Remember 80% of the current is carried
in the first 1/3 of an antenna, it is not an end to end current like an ac or dc circuit.
The conductivity of your antenna is not as important as being resonant on your operating frequency.

RF isn't always an electrical circuit.

Remember 80% of the current is carried in the first 1/3 of an antenna, it is not an end to end
current like an ac or dc circuit. The conductivity of your antenna is not as important as being
resonant on your operating frequency.

19602. Inverted Vee 3 element Wire Beam for 20 meters qrp

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-03 17:38:21 UTC
From: wb4mnk@bellsouth.net
Topic: 19602 Message: 19602

I was wondering if anyone has any information on dimensions in feet and inches for this antenna. The apex will be at 20 feet on two push up poles. The operating frequency of 14.060 mhz will be used. I can find info on a horisonal elements but not on the wire elements angled down at 90 degrees like an inverted vee.

Also any info on spacing of elements would be great.

Topic: 19602 Message: 19603

Unless my math is wrong 90 degrees is a flat dipole. 45 degrees would be an inverted V. I put “inverted V dipole” in Google and this is what I found.

http://www.hamuniverse.com/dipivcal.html

All the info you would ever need I think but I can be wrong.

Looks like that location has gone stale.

The file can probably be found at http://www.cebik.com, which you have
to register for (it's free).

Google found another location for the file:

http://www.users.on.net/~bcr/files/backyard%20wire%20antennaes.pdf

Little help please, I use 3/8 WL inverted L's, so now I'm being told that the max current is the 1st 1/3 of the wire? This is confusing because max radiation is 1/4 WL from the far end, or at least that is what my field strength meter indicates. Can someone take the fog out of my thinking?

The current on a center fed dipole (or any dipole) is illustrated thus:

http://en.wikipedia.org/wiki/File:Lambdaover2-antenna.jpg

Lots of current in the center, little at the ends. Your antenna may vary.
I never heard of a 3/8 wl antenna. I don't know where I've been.

Do you have any other antennas or is that your only antenna?

Sorry to disagree but......

Resonance is not the be all and end all, it is just where the inductive and capacitive reluctances cancel out, a 3/8 wave is good in that it offers an approximate 50 ohm load when used with good radial system, now the max current should be where the impedance is lowest which will be in the vertical section of your antenna.

As far as your field strength meter remember that you have 2 fields a magnetic and electric so you may be picking up the electric as opposed to magnetic (high current section) field.

Now saying all this I will be happily corrected by better minds in case I have it all wrong.

half wave dipole impedance is approx 72 ohms, quarter wave with good radial is 36 ohm, therefore 3/8 wave with good ground/radials will be in between the two approx 54 ohms so good match?

Sorry to disagree but ...

As far as I know, at resonance an antenna has the greatest radiation resistance, the greatest
amount of power is being converted to electrostatic and electromagnetic waves by the antenna, no?
Working with a "return loss bridge" for the last 30 years has proven this to me.
It's hard to beat a resonant dipole for efficiency. (That includes the "J" pole.)

Jo

You didn't answer my question why my 3/8 wave AV-640 vertical requires a 50 ohm to 200 ohm transformer balun.

Look at it a different way. If a 1/4 wave vertical is 1/2 of a 1/2 wave dipole, then a 3/8 wave vertical is 1/2 of a 6/8 (3/4) wave dipole. And that is not 50 ohms.

Hi Ron

I agree that resonant antennas make life easier but in Radcom May edition this year there is a review of "Duel beam pro" this is indeed a non resonant antenna and it gets a good write up.

Topic: 19580 Message: 19616

Sorry I don't know why the AV-640 requires a balun and yes I can see where the 6/8 bit comes in but I assumed the antenna in question was 3/8 wave end fed against the ground/radials. If I have it right and it is actually a dipole with each leg as a 3/8 wave I would expect the impedance to be 100 ohms. I seem to remember a graph showing impedance against wavelength in the ARRL antenna book but mine is upstairs.

Non resonant antennas that are made resonant with an external tuner work almost as good as a
resonant antenna, but never the same because of extra losses.
It very much depends on what they are comparing it to.

Just like a shortened loaded resonant dipole compared to a full sized resonant dipole is never
the same, where the reduced bandwidth imposes an additional hardship.

Jo

I would like to see that graph because I have discussions with others on antennas and never have a quick reference for impedance vs. wavelength or degrees .

19619. Re: [ham-antennas] I can not seem to unsubscribe.

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-04 22:20:37 UTC
From: Andy
Topic: 19608 Message: 19619

> ... I hit "Unsubscribe" but the mail just keeps coming.

This can happen if you've sent it from a different email address than the exact one you signed up with, or are currently registered with on the list.

If you signed up via the web (and have a Yahoo login and can remember your password), that is the more reliable way to manage your subscriptions and to unsubscribe.

Andy

19620. Re: OCFD QUESTION

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-05 01:31:25 UTC
From: k5est
Topic: 19580 Message: 19620

Hi Ron, yes'sir been using horiz loops since roughly 1977,
so up right now is a 40 meter horiz delta loop fed several
feet from a corner to lessen the rhombic effect. If you
have a horiz loop up, not much any other antenna is
needed, but the 3/8 WL inverted L is for conserving
space and its a super radiator for dxing or NVIS,
depending on where you place the maximum
radiating area. Please Google "3/8 WL antenna"
for some insight. They are much easier to match
than a low impedance 1/4 WL inverted L or vertical.
Also, I have up a 135 ft open wire fed dipole for my
reference antenna.

19621. RE: [ham-antennas] Re: OCFD QUESTION

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-05 07:40:04 UTC
From: jo barden
Topic: 19580 Message: 19621

Hi Dan

This what I have found so far about length versus impedance, I have started to look through my "Antenna book 21st ed." but not there yet but below show how 1/4 wave is 36 ohm (approx) and therefore dipole is 72 ohm and half wave is several K ohms.

backyard antennas, Peter Dodd, chapter 3, page 29 and

Jo

I would like to see that graph because I have discussions with others on

antennas and never have a quick reference for impedance vs. wavelength or

degrees .

19622. Re: [ham-antennas] Re: OCFD QUESTION

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-05 11:36:21 UTC
From: Dan Schaaf
Topic: 19580 Message: 19622

Hi Jo

Thanks for that link. I printed the graph. Then I drew a line up from 3/4 wave dipole. The line intersected at 400 ohms real and 800 ohms imaginary. Divided by 2 for vertical antenna (3/8 wave) gives 200 ohms real and 400 ohms imaginary.
That makes a lot of sense and confirms what I had thought.

19623. Re: Inverted Vee 3 element Wire Beam for 20 meters qrp

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-05 13:27:22 UTC
From: amicom_ro
Topic: 19602 Message: 19623

Look in the book: "73 Vertical, Beam and Triangle Antennas" by Edward M. Noll, W3FQJ, fourth printing - 1976, publishing house: Editors and Engineers.

In chapters 43, 44, 45 and 46 you'll find the informations about inverted Vee wire beams.

If you can not find the book, I can send you via email some photos of the respective chapters.

73 de Gabriel,
yo3cen

>
> I was wondering if anyone has any information on dimensions in feet and inches for this antenna. The apex will be at 20 feet on two push up poles. The operating frequency of 14.060 mhz will be used. I can find info on a horisonal elements but not on the wire elements angled down at 90 degrees like an inverted vee.

19624. Noise!

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-05 13:35:11 UTC
From: radiotech750
Topic: 19624 Message: 19624

I hope the members of the group can help. I have a noise problem. Let me give some background on this. I always had some low level noise in my receivers (SWL). About a week ago the noise level went up to high levels that some station became buried in it! The antennas are a 200ft long wire and a 50 foot slinky Antennas are grounded and so are the radio into a common ground to an 8ft copper rod. I thought it might be line noise but radios get the same noise on batteries. I unhooked the antennas and tried the radios on their whip but that had no effect.
Any help will be appreciated

Ernie
Kc8yoq

19625. Re: [ham-antennas] Noise!

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-05 13:42:14 UTC
From: Dan Schaaf
Topic: 19624 Message: 19625

Maybe it is line noise on the AC mains running down the street. Sometimes transformers on the power lines get noisy after heavy rains.
Maybe a neighbor has a noisy A/C unit that is radiating.
Maybe a neighbor has a Plasma TV. These radiate noise.
It could be any number of things.
You might have to get yourself a portable radio and walk/drive the roads looking for a peak in the noise to find it's source.

Best Regards
Dan Schaaf

Subject: [ham-antennas] Noise!

I hope the members of the group can help. I have a noise problem. Let me give some background on this. I always had some low level noise in my receivers (SWL). About a week ago the noise level went up to high levels that some station became buried in it! The antennas are a 200ft long wire and a 50 foot slinky Antennas are grounded and so are the radio into a common ground to an 8ft copper rod. I thought it might be line noise but radios get the same noise on batteries. I unhooked the antennas and tried the radios on their whip but that had no effect.
Any help will be appreciated

Well I would say the first thing is to make sure it is not coming from in the house. Shut off your main power at your service panel so there is nothing in the house on. If you still have the noise than it is time to go out side sniffing to see what you can find.

I had a similar problem and that's exactly what me and few ham buddies did. The problem was noticeable over a 5 mile radius. Called the power company, they came out and found a branch had fallen on the power lines and it was right next to the transformer causing the noise. Branch came down and the noise went away. Good luck!

Maybe it is line noise on the AC mains running down the street. Sometimes transformers on the power lines get noisy after heavy rains.
Maybe a neighbor has a noisy A/C unit that is radiating.
Maybe a neighbor has a Plasma TV. These radiate noise.
It could be any number of things.
You might have to get yourself a portable radio and walk/drive the roads looking for a peak in the noise to find it's source.

Power lines are great transmit antennas for noise. Long and the gridwork of them makes it hard to narrow the source.
Perhaps someday I will find a way to couple 160 meter signals to/from the power lines to work 160 DX HiHi

Any new devices in the shack or house?
My girlies mobile phone charger is a very noisy one ... so if I am on the radio I have her strikly forbidden to charge the phone :-)
It can be a sat receiver or something from pc or phone (your dsl router?)...
any switching power supply (printer of pc etc ... can be the same but in a neighbour house down the street...
A tv set from a neighbour
A motor with bad brushes ...
Take a portable radio and walk around in your area ... maybe you find the source ... good luck

A way to couple to it??? A capacitor that can stand the voltage on the line
... and that has enough capacitance to couple your 160m signal ... and not
so much capacitance that it couples the ac voltage ...
But be aware of the danger
Power lines are supposed to kill people
(don□t try this at home)

Ernie

I hope you have better success with your power company than I have with FPL here in FL.
All sniffing will happen faster if you can do it yourself and then call an Electric company out and show them where the problem is located.
They generally have bigger fish to fry than worrying about a ham operator.
Now, if you run an EMCOMM station, you might tell them so and maybe they will be more responsive.

This web site has the dimensions of an inverted V. There is a small program you can download that works very well.

Look in the book: "73 Vertical, Beam and Triangle Antennas" by Edward M. Noll, W3FQJ, fourth printing - 1976, publishing house: Editors and Engineers.

In chapters 43, 44, 45 and 46 you'll find the informations about inverted Vee wire beams.

If you can not find the book, I can send you via email some photos of the respective chapters.

You don't say what the noise sounds like, it's period or duration.
Several sources of radio frequency noise include:
Cracked (damaged) power line insulators.
Electrical and electronic equipment. (TV receivers, transmitters, chain saws and such)
Electronic lighting equipment. (especially curly fluorescent lamps)
Rubber belt driven equipment.
Our sun and Earth's surface weather.

Many times such noises can be found by turning off everything electrical in your house.
If it's not in your house you can frequently locate it by tuning between radio stations on an AM
radio, (hand held or in a car - between .54 and 1.7 MHz) tune for the most noise and go from your
place up and down the street or road that you are on, around the block around several blocks.
Many forms of noise travel on the power lines or on the power line ground wire and repeat giving you
maximums and minimums repeated many times up and down the street.
To pinpoint many noise generators you must point the ferrite-loop in a portable radio at suspicious
areas, such as possible insulators or frayed wires. (causing corona) When the center of the ferrite
rod is pointed directly at the noise source the audible noise will null. You are the detective!
If that fails a 300 MHz AM receiver with a directional antenna may be needed.

Have you sent an email to:

ham-antennas-unsubscribe@yahoogroups.com

With subject unsubscribe and text of unsubscribe? MAKE SURE it is from the SAME email/isp you signed up from. Say at work instead of home, etc.

I had that problem with a list that was very infrequent when an isp changed names and the list 'exploded' message wise. Finally got a totally different isp and that killed it as far as I was concerned. They 'forwarded' the emails for 2 years after the change over in isp names.

Hi,

  Do not forget to add to your list of noise contributors such things as: wireless routers, older type computer monitors, wall wart power supplies.

   My linksys wireless router's CPU will cause "blips" on 20 meters easily - about every 35 to 45 KHz.

You don't say what the noise sounds like, it's period or duration.

Several sources of radio frequency noise include:

Cracked (damaged) power line insulators.

Electrical and electronic equipment. (TV receivers, transmitters, chain saws and such)

Electronic lighting equipment. (especially curly fluorescent lamps)

Rubber belt driven equipment.

Our sun and Earth's surface weather.

Many times such noises can be found by turning off everything electrical in your house.

If it's not in your house you can frequently locate it by tuning between radio stations on an AM

radio, (hand held or in a car - between .54 and 1.7 MHz) tune for the most noise and go from your

place up and down the street or road that you are on, around the block around several blocks.

My recommendation is to try to find it as best as you can. When I called the power company, I guess I'm fortunate, they were very cooperative and listened to what I had to say but they did want to know if I had done any research myself, they also asked me to shut off all of the power to my house and run the radio on batter to see if that helped. Another thing I got lucky on is the power company has a ham work for them, and he was the one who came out and sniffed it out. Power line noise can travel a great distance and they do want to know that you've narrowed it down as best as they can.

He told me of one call he had on reported noise was narrowed down to a doorbell at another house.

Art,

After doing research and reading my antenna books this is what I have come up with as far as dimensions and lengths, your horizontal section will be your 20M dipole section 33.5' long, your middle element will be 33.5' long (overall), your first element will be 30' long (overall), your third element will be 40' long (overall).

```
/\-----/\-----/\
30' 33.5 40'
<------33.5----->
```

I am not sure if two coax feed points at the middle is what is required or if ladderline will work. Me I believe ladder line will work the best. all I can say is try this and analyze and see what you get.

Another tool is a handheld scanner, connected to a small (three or 4 element) VHF beam. Tune the scanner to the top of the aircraft band, appx. 134 MHz so it'll be receiving in AM and aim the beam at suspected noise sources. Just have to make sure that the antenna still has a usable pattern, since it is designed for 146MHz. and may show an odd pattern at 134MHz.

Between that and the AM portable you should be able to track down the source.

Also, read up on "triangulation", a method of localizing a source from a distance. Sometimes necessary if the field of noise is too big to pin down.

Good hunting. and, by all means, make sure that your own house is clean.

Stan

Hi
Have been reading ARRL Antenna Hanbook. Interested in the section on Open Sleeve Antennas. Understand theory but looking for specific designs; using a google search was not helpful.

Can anybody point me in the direction of specific open sleve anntena designs, I am particularly looking for a WARC bands antenna, pefererably a vertical.

Many thanks.

Topic: 19624 Message: 19643

That last part really should be where you start. Many hams believe they have a 'clean QTH', they can't possibly be their own source of noise.

I was one of those. I had been plagued by severe noise starting at 40 meters, worse at 80 meters, and 160 meters was completely unusable. I had 20-30 over S9 of noise on 160m, and at least S9 day and night on 40/80.

I contacted the power company, and they found a few trouble spots and repaired them...I still had noise; a bit less on the other bands, but no change on those I noted.

So with my son's help, we tripped all the breakers in the house, with the exception of the ham shack, and I stayed at the shack to monitor. What a miracle - the noise was gone! As he turned back on each breaker one by one, we found which one was causing the noise. It was in our spare bedroom - at the extreme opposite end of the house. Next, he unplugged everything one by one in that room, until I told him which one made the noise stop.

My wife's desktop PC was found to be the culprit. We brought the PC to the ham shack, and the instant I turned it on, the HF bands were full of noise. The fix was easy, I started with the obvious - the power supply. As soon as I replaced it, the PC was back in service, and my noise was gone. If I had a 160 meter antenna, I could actually use that band!

Afterwards, I shut off all the breakers, including the ham shack, and listened to my HF rig with a UPS battery (not with the UPS - just the battery). Scanning the bands with the shack's breaker on, and with it off, showed no change - so I was lucky there.

I'm still plagued with noise though, depending on where I aim my beam, and if it has been raining or not. It drives me nuts that my mobile rig just 5 feet away from my shack rarely has any noise. I've tried different rigs on different antennas, so the problem isn't there. I still have more work to do in searching for noise.

Hi Chris

Thank Mr Google! it just showed the graph I was looking for, but saying that it is a good source of information. I must admit that my forced inactivity work wise has got me into the theory more as it keeps the grey cells going. Still learning this end but truth be told I am much better at power factor correction or compliance with the IEE regs than some of the complex stuff.

Hope to catch you on the bands

I'm not a beam expert, but my books say the close presence of the other two elements lower the
impedance of the driven element from 73 Ohms to sometimes as low at 9 Ohms, this is why gamma, delta
matches and step down balun transformers are used to match it.

The element dimensions may be altered by the spacing between elements and whether the elements
are connected to the boom or insulated.

The gain of the beam is strongly altered by the length of the boom, but if you just extend the
boom and move the two end elements out to the ends the gain goes up just as if you had added
elements to make a three element beam into a five element beam.

Beam gain and front to back ratio seem to be apposing goals, increasing one always seem to reduce
the other. Both are equally important.

A two element Moxon beam has the gain of a three element conventional beam and probably better
back ratio. Just trickier to support.

Unfortunately any cable coming into the house, even grounded wires, can bring in noise from external sources, keep looking. Don't waste time waiting on anyone else.

O you bet! BUT if I offer assistance they(the Techs) usually take offense!
it has happened to me before when I saw a cable tech doing something wrong
!!

19652. Cushcraft MA5B swr issues.

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-05 22:53:59 UTC
From: w9nfl
Topic: 19652 Message: 19652

Hello,

I'm having swr problems with my MA5B and wonder if anyone has experience with this antenna. I've rechecked all my measurements and they seem correct. Even turned the traps around in case of them being labeled incorrectly.

Any help/comments are welcomed via this group or by my email.

Thanks, Keith W9NFL

Y'might want to look at the cable co's ground connection at the base of the pole (if there is one). Mine was crappy and loose.

No but:
<<
In addition to my review of how to repair the trap shorting out problem a new problem came up.
I started getting momentary hi SWR reading all bands then yesterday they all went high very high.
It turns out that the matching network box opened up. The SO-239 female chassis connector takes
the cable shield side into the box via a bolt solder

lug washer and nut on the inside of the box. Corrosion of the solder lug caused the shield side
to open up. This could have been fixed with cleaning the solder lug which I did but I also soldered to the SS Steel bolt as well. Easy fix.

It might be worth some preventive maintenance on this if you have the antenna down.

Subject: Re: [ham-antennas] Noise!

That last part really should be where you start. Many hams believe they have a 'clean QTH', they can't possibly be their own source of noise.

I was one of those. I had been plagued by severe noise starting at 40 meters, worse at 80 meters, and 160 meters was completely unusable. I had 20-30 over S9 of noise on 160m, and at least S9 day and night on 40/80.

I contacted the power company, and they found a few trouble spots and repaired them...I still had noise; a bit less on the other bands, but no change on those I noted.

So with my son's help, we tripped all the breakers in the house, with the exception of the ham shack, and I stayed at the shack to monitor. What a miracle - the noise was gone! As he turned back on each breaker one by one, we found which one was causing the noise. It was in our spare bedroom - at the extreme opposite end of the house. Next, he unplugged everything one by one in that room, until I told him which one made the noise stop.

My wife's desktop PC was found to be the culprit. We brought the PC to the ham shack, and the instant I turned it on, the HF bands were full of noise. The fix was easy, I started with the obvious - the power supply. As soon as I replaced it, the PC was back in service, and my noise was gone. If I had a 160 meter antenna, I could actually use that band!

Afterwards, I shut off all the breakers, including the ham shack, and listened to my HF rig with a UPS battery (not with the UPS - just the battery). Scanning the bands with the shack's breaker on, and with it off, showed no change - so I was lucky there.

I'm still plagued with noise though, depending on where I aim my beam, and if it has been raining or not. It drives me nuts that my mobile rig just 5 feet away from my shack rarely has any noise. I've tried different rigs on different antennas, so the problem isn't there. I still have more work to do in searching for noise.

Dan,

Soldering stainless steel, using silver bearing solder (lead free solder, the type used now for soldering potable water supply copper pipe) and a special liquid flux for low temperature soldering of stainless steel, such as the type made under the "Stay Clean" brand, is just as easy as soldering copper with rosin type flux and convential solder. The special type flux is available at most hardware stores or welding supply shops. You can also solder copper to stainless at low temperatures. The trick is to use only low temperature, or controlled temperature, soldering irons. Using a torch is much too hot, and the joint will turn black and be a very poor electrical connection. As with all soldering, be sure not to inhale any of the fumes from this liquid flux. Any flux residue is easily cleaned off after the soldering is complete.

Soldering to SS is as easy as soldering any other metal if you use the right flux. Right now I use Oatey Liquid flux , bought at my local Ace hardware store in a nice little 4 oz bottle. When I was working I used Ruby Fluid but not all stores carry Ruby brand. I have been soldering to SS on and off for 45 years.

I once had a brand new GE dishwasher that when operating generated an S-6 noise level on the ham bands.

It was horrid. I had a big fight with GE repair and warranty to get them to put the fixes in place. Finally got a repair person to come out and then instructed him how to minimize the problems. He was understanding and by him doing the work it did not void the warranty.

  Maybe we need to start a list of all items by manufacturer, model and noise level as well as resolution.

If I had a 160 meter antenna, I could actually use that band!

Afterwards, I shut off all the breakers, including the ham shack, and listened to my HF rig with a UPS battery (not with the UPS - just the battery). Scanning the bands with the shack's breaker on, and with it off, showed no change - so I was lucky there.

I'm still plagued with noise though, depending on where I aim my beam, and if it has been raining or not. It drives me nuts that my mobile rig just 5 feet away from my shack rarely has any noise. I've tried different rigs on different antennas, so the problem isn't there. I still have more work to do in searching for noise.

The nulls off a ferrite antenna typically found in an AM radio are off the ends, not broadside as you claimed.

Subject: [ham-antennas] Re: OCF Antenna Question

Tony,

The quality of the balun is the major cost driver and, of course, wire quality can also impact cost. The balun design/construction can have a impact on performance characteristics and the long term reliability of the antenna.

I built my own OCF cut for 80m and it has low SWR on 80-40-20-17-12-10-6, but worthless on 15m. SWR is under 2.2:1 everywhere on those bands - actually under 1.5:1 most places I operate, but I normally use a tuner anyway. My dual (4:1 impedance and 1:1 current since the OCF will tend to send RF back to the shack) balun was about $100 since I did not build it and I run up to 800W through it so bought a 2kW rated balun.

You can do a little research, but I've seen 4:1 recommended for installations less than 40' high and 6:1 for higher than 40' in order to properly match a 50 ohm feedline to the antenna impedance. Mine is pretty much flat top now at about 28', but I plan to raise the center another 5' or so.

You know if you use the “Ugly Balun” it will keep RF out of your shack. I used just more coax for mine and not connectors and it works great.

Multiband beams are not cheap
Sometimes you can find a used tribander for abt. 100 bucks
But not he best one and it is used ... so if cost is to be kept low I would use a wire antenna first to get on the air ... after that you can improve your station with tower, beam, rotor etc ... but all tat would cost you an arm and a leg compared to the wire antenna ..... so ...
To get on the air I woul recommend a ladderline fed doublet (or if you have room and some trees or wodden poles a loop)

I second that, You can make an "ugly" 1:1 choke balun from 10turns (ish) @ 6-8'' dia under the aerial feed. I also use a similar choke of 30t @ 40mm dia tube at the ATU to ensure RF is tamed!

From: dean
Topic: 19668 Message: 19678

I'm not familiar with that radio. Is it tube or solid state. If its tube you have to tune the frequency with your radio or you can use an external tuner. I personally would rather make a resonate antenna that does not require much tuning rather than put a lot of bucks out for a tuner.

What kind of radio do you have? Does it have an internal tuner? What frequencies do you want? How much space do you have? You can build a nice multiband inverted V for cheap. Use an "Ugly Balun" and that can save you bucks also.

http://www.hamuniverse.com/balun.html

If you cut your wires right you might not even need a tuner.

19679. RE: [ham-antennas] Newbie Question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-06 22:42:52 UTC
From: Richard Schmuke
Topic: 19668 Message: 19679

Walt a small beam $200 to $500 dollars , a small rotor $500, a small tower and supplies, base and cables $1000, so you are close to $2000 and you are not on the air yet.

Wire and a balun for a $100 and you are on the air. If you scrounge and build then about $29 to $50. A wire antenna can be held up with anything non conductive. Double braided , extra treated Dacron is good but some nylon cord from Wal-Mart will work. It might not last 20 years but believe me you will change antenna designs more often than that.

Rich , Kd0zz

Subject: [ham-antennas] Newbie Question

As a new member, I want to ask the group what a reasonable multiband beam (2 or 3 element)will cost me. I am on a shoestring. Or would I do better with a wire/balun setup for cost purposes? Thanks for any ideas.

Walt

Solid State with digital readout. 100 watt output nominal. Understand about the antenna and having one that resonates properly.

Thanks

19682. Lightning Protection in my Transmission Line

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-06 23:07:44 UTC
From: m0tim
Topic: 19682 Message: 19682

My antenna transmission line runs underground from the wire antenna to my basement radio room in plastic schedule 40 conduit and through the concrete wall.

I want to put lightning protection before it enters the house and have a plastic wall mountable Harger case and Polyphaser lightening arrester.

The problems is that there is no room on the outside wall where the conduit enters the house to mount the case, the nearest I can get is 6 feet away. I want to avoid having to move the exiting conduit so my plan is to put a sched 40 tee piece in just where the coax enters the house run the cable 6 feet to the Harger box and the arrester and then run it back down the same 6 ft of sk 40 to the entrance hole.

My question is if this negates the whole purpose of the lightening arrester. Would teh lightning just across from one cable to the other and just bypass the arrester?

Thanks and 73

Tim K9VB

Subject: [ham-antennas] Lightning Protection in my Transmission Line

My antenna transmission line runs underground from the wire antenna to my basement radio room in plastic schedule 40 conduit and through the concrete wall.

I want to put lightning protection before it enters the house and have a plastic wall mountable Harger case and Polyphaser lightening arrester.

The problems is that there is no room on the outside wall where the conduit enters the house to mount the case, the nearest I can get is 6 feet away. I want to avoid having to move the exiting conduit so my plan is to put a sched 40 tee piece in just where the coax enters the house run the cable 6 feet to the Harger box and the arrester and then run it back down the same 6 ft of sk 40 to the entrance hole.

My question is if this negates the whole purpose of the lightening arrester. Would teh lightning just across from one cable to the other and just bypass the arrester?

Thanks and 73

Tim K9VB

Actually, Tim, the lightning arrestor deals with strike energy on the center conductor of the cable, shunting the majority of that particular part of the strike to the shield and then to ground. So, the input circuits of the attached radio are spared the blast. Given that description, I'd put the arrestor right on the antenna jack of the radio, or tuner if you use one.
It is typically not a good idea to run the antenna side of the cable next to the radio side of the cable, but for a different reason. The strike current on the antenna side of the outside of the shield will set up a magnetic field which will induce a voltage on the radio side of the cable - transformer action. My reference here is where you were intending to install the arrestor on center of the loop of cable, assuming that that point would be tied to your lightning ground.
If you have a way of accessing the cable somewhere before it enters the building, I'd tie that point to my grounding system via a short fat lead with very gentle bends if necessary. In a way, running the cable underground will help to soften the strike by the cable's capacitance to the earth. Some of the higher frequency energy will be shunted off the shield.

Stan

19689. RE: [ham-antennas] Newbie Question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-07 02:30:29 UTC
From: Richard Schmuke
Topic: 19668 Message: 19689

To start, you don’t need a balun or anything complex , just put up a dipole cut for 20M band and you are on the air. As you feel comfortable with the radio you can add the tuner and balun. The only reason I say start with a dipole is that it is simple and you want to have fun right off the bat. As you get a good feel with the radio then things can get more complex and you will always have this group the ask questions of as you go. I build all my stuff, antennas, baluns and towers but then like good ole Waylon Jennings said, “I have always been crazy but it kept me from going insane”.

To: ham-antennas@yahoogroups.com <mailto:ham-antennas%40yahoogroups.com>
Subject: RE: [ham-antennas] Newbie Question

Walt a small beam $200 to $500 dollars , a small rotor $500, a small tower and supplies, base and cables $1000, so you are close to $2000 and you are not on the air yet.

Wire and a balun for a $100 and you are on the air. If you scrounge and build then about $29 to $50. A wire antenna can be held up with anything non conductive. Double braided , extra treated Dacron is good but some nylon cord from Wal-Mart will work. It might not last 20 years but believe me you will change antenna designs more often than that.

Rich , Kd0zz

Subject: [ham-antennas] Newbie Question

As a new member, I want to ask the group what a reasonable multiband beam (2 or 3 element)will cost me. I am on a shoestring. Or would I do better with a wire/balun setup for cost purposes? Thanks for any ideas.

Walt

19690. New to the group with questions

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-07 03:00:58 UTC
From: pchapman920
Topic: 19690 Message: 19690

HI:

Paul WA4NUN here. Ham since 1962, same call. Have a bit more time on my hands than in the past although somewhat active over the last few years. I run an Icom 7410 as the new gear and my 718 is now the back-up if needed. Trying to move toward more resonant antennas that work with the internal tuner of the 7410.

Operated for several years with a Van Gordon G5RV sold at HRO which is no longer in production. It was a decent compromise antenna that worked pretty well on 20 and OK on other bands. (A bit noisy.) It failed recently to UV rot and heavy wind strain (the dacron rope after all this time still has very little fraying and will be reused) at the center split after eight years, but most of the coax (with minor bleeding but meter tests good) and copper wire was good for salvage. I do not want to be one antenna dependent any longer.

Forgive the extreme detail but I know it can be tough to answer questions without enough information.

I have a very large lot and no HOA to deal with, but still have space restrictions as the lot is very heavily wooded and the house is on top of a fairly steep hill. I have about 120 foot diameter circle of trees to work with and most do not qualify as good, stable, antenna trees. I have one good tall tree I could use as an anchor tree for two or three antenna ends and basically spin around the compass to other trees. I already have a 40 meter dipole with a 1:1 balun up, that is working great, just need to do final trim and weather seal, also a K4TR version of the W5GI mystery antenna ready to go, and a 20 meter double bazooka ready to go when it drys out from the tropical storm that came through over the last few days here in Georgia. On a compass the spans would be about 50 degrees apart at the far end for each antenna, so there would be no true right angles which is desired, of course.

Implications of this approach?

Next....I have some flexibility with the exception of the "Mystery Antenna" about spacing the feed-line splits from each other, roping closer to one tree or the other, and there will be some height difference at the splits of course as well. As I see it from the ground prior to install going clockwise, the 40 meter dipole feed split would be about 40 feet from the Mystery Antenna feed split at about plus or minus 10 feet in height from it. The 20 meter Bazooka feed split would be about 30 feet from the 40 meter dipole split and about 40 feet from the Mystery Antenna split.

I need the Mystery Antenna to stay in touch with a friend on 75 and do not have enough room to run a full 1/2 wave dipole. I want to experiment with the Bazooka, and if unhappy, once I finish tuning the 40 meter dipole, just start adding legs to it for multi-band.

Which brings up another question. Has anyone added a 17 meter leg to a forty meter dipole with balun and get by with an internal tuner that is only reliable to tune not worse than a 2:1? I've done it with 20 meters which was easy many years ago, after I tweaked the forty perfect flat without a tuner. If I remember correctly, also 15 meters, and I think I had a 1:1 balun in the middle of it all as well. Back then, 17 meter band did not exist.

Thank you for reading my questions and I look forward to any help you folks can give me as I want to move forward on this project by Thursday, after it dries up here in a day or two.

19691. How to get feedline away from the roofing shingles on the house?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-07 03:20:40 UTC
From: pchapman920
Topic: 19691 Message: 19691

My previous antenna was bad about rubbing the shingles on the house as I do not have gutters.....I use drip edge....no gutter....no clutter, but I have to replace a couple of shingles on the bottom due to the rubbing. A couple of ideas I came up with were

1. Use an ornamental iron plant hanger on the facia board to get the feedlines away from the shingles. Metal might create an unwanted field of interference?

2. Partially bury a concrete block on top of gravel with a second cemented on top and use a length of schedule 40 with drain holes above the blocks for redundant draining on the bottom and a T above the drain holes to pick up the feedlines, and screw a band around the schedule 40 at the facia board to hold it in place leaving enough above to get beyond the roof rub area?

Suggestions or confirmations much appreciated.

Topic: 19691 Message: 19692

solution depends on what type feed line you have and antenna type and location . If you are usind RG8 the PVC pipe is a good solution however do not use a Tee , use electrical conduit with a sweeping curve so that you do not have to make any 90 degree bends in the coax . as that can cuase some types of coax to short internally . the ornamental plant hanger will not affect coax but do not use it if you are using window twinlead . I have a 40 ft pushup pole with a 90 degree corner brace clamped to the top section with 2 screw type hose clamps attached to the facia board with a standard antenna mast mount , the pole is about 4 inches stand off from the roof edge . the lower end of the pole is buried in the ground about 8 inches deep and is solid unough to support the dipole and a 17 ' tram FM vertical . there is a marine grade pulley in the outer screw hole on the bracket and I pull the dipole up and down like a flag . the coax just drops straight down and goes into the basement through a 2 " electrical conduit . when I had the G5RV and 450 ohm line I used the same arrangement except I brought the line in through a window , it was thin enough I could close and lock the window on it , old fashion 1930's wood double hung windows .

I agree with Rich. Keep it simple at first and then start your digging and research after your on the air. You can also get lots of info on the air from hams and get first experience on how the antenna sounds. I run a fan dipole, inverted L, and a 80 meter doublet. The fan dipole is by far the best antenna I ever built. It works great. It covers 80, 40, 30, 17 meters. It does take up a little space but it is all inverted vee style. When I started out I started with a G5RV and it worked great. I still have it today and use it in my to-go box. The only reason I took the G5RV down was to repair it and I put the 80 meter doublet up in its' place. I one thing I don't understand is the talk about putting a balun on a resonant dipole. Any way hope this helps out.

Subject: RE: [ham-antennas] Newbie Question

Walt a small beam $200 to $500 dollars , a small rotor $500, a small tower and supplies, base and cables $1000, so you are close to $2000 and you are not on the air yet.

Wire and a balun for a $100 and you are on the air. If you scrounge and build then about $29 to $50. A wire antenna can be held up with anything non conductive. Double braided , extra treated Dacron is good but some nylon cord from Wal-Mart will work. It might not last 20 years but believe me you will change antenna designs more often than that.

Rich , Kd0zz

Subject: [ham-antennas] Newbie Question

As a new member, I want to ask the group what a reasonable multiband beam (2 or 3 element)will cost me. I am on a shoestring. Or would I do better with a wire/balun setup for cost purposes? Thanks for any ideas.

Walt

You have received some very good advice here. Just remember the perfect antenna is the one that fits your budget and your QTH . As a 30plus year Ham I have only seen one antenna installed exactly the way the book called for it. As a novice I had a 50ft tower and a 4ele. tri band antenna and a 40/80 trap dipole before I ever got my license back. I was converting over from a large CB set-up so the tower was there and I already was familiar with swapping and trading . I have always bought Swap fest towers for about $50.00 per section , that's $250.00 for 50ft. I just purchased another large triband for $100.00 . The array does not have to cost an arm and a leg. I had been a Ham over 20 years before I owned a tuner . Learn resonate antennas and how to resonant them . Chuck Wq5B

Subject: RE: [ham-antennas] Newbie Question

To start, you don’t need a balun or anything complex , just put up a dipole cut for 20M band and you are on the air. As you feel comfortable with the radio you can add the tuner and balun. The only reason I say start with a dipole is that it is simple and you want to have fun right off the bat. As you get a good feel with the radio then things can get more complex and you will always have this group the ask questions of as you go.. I build all my stuff, antennas, baluns and towers but then like good ole Waylon Jennings said, “I have always been crazy but it kept me from going insane”.

19699. RE: [ham-antennas] New to the group with questions

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-07 13:01:51 UTC
From: Richard Schmuke
Topic: 19690 Message: 19699

Subject: [ham-antennas] New to the group with questions

HI:

Which brings up another question. Has anyone added a 17 meter leg to a forty meter dipole with balun and get by with an internal tuner that is only reliable to tune not worse than a 2:1? I've done it with 20 meters which was easy many years ago, after I tweaked the forty perfect flat without a tuner. If I remember correctly, also 15 meters, and I think I had a 1:1 balun in the middle of it all as well. Back then, 17 meter band did not exist.

I did it with my antenna. The only advice I would add is to make the 17M leg a little long as then tweak it in. It will react to the 40M leg depending how close it is so an exact length is different for each application. I also had 20M between them.

From: dean
Topic: 19690 Message: 19700

I have two inverted V's at my house. I used to think it was a fan dipole but its two dipoles perpendicular to each other. At any rate they will tune with a external tuner on 6 to 80 M. The internal tuner will tune the antenna on 75,40,17,15,12,10. All it is is 80 Meters, N – S and 40 Meters, E – W. Works great but I also have a lot of room. I can't use most of my property for antennas as the property is not flat. I also have a beam for my 20 meter work but when hitting a lot of people in different parts of the country a dipole works great.

Date: 2011-09-07 13:55:52 UTC
From: dean
Topic: 19668 Message: 19701

Just remember if you don't feel like making the "Ugly Balun" just take 8 to 10 turns of your coax to make a balun and that will keep the RF out of your shack. You can also use just RG-8X and it'll work just great also. I'm using LMR 400 but that is just me.

To: mailto:ham-antennas%40yahoogroups.com
Subject: RE: [ham-antennas] Newbie Question

To start, you don't need a balun or anything complex , just put up a dipole cut for 20M band and you are on the air. As you feel comfortable with the radio you can add the tuner and balun. The only reason I say start with a dipole is that it is simple and you want to have fun right off the bat. As you get a good feel with the radio then things can get more complex and you will always have this group the ask questions of as you go.. I build all my stuff, antennas, baluns and towers but then like good ole Waylon Jennings said, "I have always been crazy but it kept me from going insane".

Rich ,KDØZZ , ☺

Subject: Re: [ham-antennas] Newbie Question

Thanks for the advice. I am compiling what everyone says here. So far the wire/Balun is the choice of the majority. Thanks for the input.

From: Richard Schmuke
Sent: Tuesday, September 06, 2011 6:42 PM
To: mailto:ham-antennas%40yahoogroups.com <mailto:ham-antennas%40yahoogroups.com>
Subject: RE: [ham-antennas] Newbie Question

Walt a small beam $200 to $500 dollars , a small rotor $500, a small tower
and supplies, base and cables $1000, so you are close to $2000 and you are
not on the air yet.

Wire and a balun for a $100 and you are on the air. If you scrounge and build then about $29 to $50. A wire antenna can be held up with anything non conductive. Double braided , extra treated Dacron is good but some nylon cord from Wal-Mart will work. It might not last 20 years but believe me you will change antenna designs more often than that.

Rich , Kd0zz

Subject: [ham-antennas] Newbie Question

As a new member, I want to ask the group what a reasonable multiband beam (2 or 3 element)will cost me. I am on a shoestring. Or would I do better with a wire/balun setup for cost purposes? Thanks for any ideas.

Walt

19703. Re: Lightning Protection in my Transmission Line

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-07 14:47:10 UTC
From: daverickmers
Topic: 19682 Message: 19703

I have a Diamond pill type arrester outside on a plate attached to my ground system. Can't you put the Polyphaser at the drip loop and Tee off to Antenna and Ground? I wouldn't risk letting lightning get too close to the radio.

Topic: 19682 Message: 19704

If you have soil aroung where the conduit goes through the basement wall like I do set a metal or a treated 4x4 post and mount teh box to it . I have not mounted my arresters yet but will probably attach them to the lower section of the push up pole . I usually just disconnect the antennas where the cozx enters the basement and drop the coax on the ground in the yard .

Gents... and ladies, too;

The farther away the lightning arrestor is from the radio, or what ever you're protecting, if you're working with coax, will loose its effectiveness.

I'll share something I was ignorant of, but when explained it was a "I could've had a V-8" moment.

If you take a long piece of coax, tie the shield and center conductor together at the end away from the radio and then zap that point with a large voltage spike to ground what will happen?

Even though the coax is grounded at the radio end, you can still have a destructive spike delivered to the radio. HOW, you ask??

It all has to do with the "velocity of propagation" (Vp) through the cable. That's that pesky bit that has to be figured in when doing phasing line and 1/2 wave balun designs.

What it (Vp) does is to delay the delivery of the spike at the radio end. At the antenna end (where we put our short) the spike is in phase on both the shield and center conductor. But at the radio end, the shield spike will arrive first and make its way to ground, you did ground the radio chassis, right? Then the delayed center conductor spike shows up.

So what you say!! Well, if you hit both the radio chassis AND antenna input at EXACTLY the same time with the spike, the DIFFERENTIAL (and it is always the differential that kills you) will be ZERO. But, crank in the delay through the cable and you now have... DIFFERENTIAL across the radio's antenna input... and POOF! There goes my "hears a pin drop on Mars" sensitivity.

So, the arrestor is placed at or near the radio's input do deal with that differential. Install it closer to the antenna and the cable between the arrestor and the radio will be able to re-create the differential spike with possibly poor results.

Oh, and reference the DC grounded antenna designs... For lightning, they are the same as the short we introduced in our science experiment above. But consider this; at the frequency of interest, 2 meters, twenty meters, etc. they are NOT shorted! Otherwise they wouldn't work too well.
That's why a nearby strike can induce a pulse into your antenna and its own internal tuning circuits will produce a pulse of strike energy to your radio.

That's how PolyPhaser told it to me...

Stan

We've been through this before!

The only positive way to protect your radio from lightning is to disconnect it when it is not in use.

They can even be destroyed by a powerline hit!

I had 4 years of lightning protection experience working for NASA in the 80's.

19710. Need a Filter! (was NOISE)

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-07 23:39:16 UTC
From: radiotech750
Topic: 19710 Message: 19710

Well the cable guy was here and in his words(there is nothing wrong with the cable or ground".
I did some more RF snooping and found about 30db of noise coming from each cable box in the house! I was told there is nothing we can do about that!
Is the a filter out there to get rid of this hash noise?

thanks
Ernie

Question what company is it? Comcast, Att, or other
If it was Comcast than they sent a contractor... and they dont know jack
from the back of there hand. all you have to do is call them back and tell
them you want a "In House Tech" they know about line noise and leakage.
Att's techs are not contracted out (Union), so all you have to do is ask for
another more qualified tech.
Others may very sorry.

Then threaten them with the FCC too. Yeah now days that probably won't
do much. But I knew a time in the 80's where i had horrid power line
noise and after like 3 years of complaining I made a simple tape
recording showing how bad it was and sent it off to the FCC and less
than a month later I got a letter back from the FCC saying the power
company should be in the area in a week or so to fix it. and they did.

Also as a ham you have the right to have an RFI free home, if the box that you rent is causing rfi than you have the right to bug the hell out of them till they fix it!
I had a problem with my Comcast internet that took 16 calls 31 techs (9 house and 22 contractors, five of those contractors I had to toss out of my house) and over a year to fix!
I gave up switched to att 6 months into the problem. 6 months later comcast called me and said it was fixed and would I like to become a customer again... No thank you, not after that mess.

As I said: "The noise can come into your house on grounded wires" such as the shield of coaxial
cable. (which in the air, between poles acts like an antenna) No filter can filter that. Anything
IN the cable will not likely jump out and effect your HF reception. (just leaks slightly at any baluns)
You should have kept looking instead of waiting.

As has already been said here...The only effective way to protect your gear is yank the antenna and unplug it.

That being said, thought I would add my 2 cents from age old training a few decades ago. When you ground your gear in the shack, use the same gauge and brand wire for all equipment going to the buss bar. The old school I came from said use all the same same size for all common devices in an area and increment it as it heads toward the final ground termination point. It is a mild form of added protection, but it would not make sense to have a #18 ground going to one rig and a #10 to another, or stranded to one and solid to another. Nothing will insure against a pure hard strike, but if on the more minor side, this practice in theory helps to prevent what the instructors called "Backblow" The idea is to create the most conductive path to the place it will do the least amount of harm which is smaller gauge to larger gauge. I disagreed in part with the instructor stating that in my my mind the total combined gauge of all device grounds should be less that the ground wire leading leading to the final terminating ground, which to me means that the terminating ground wire should be a #4 wire, but they were hung up on #6, which I am using now. I found a length of #4 in the garage last week, which I will install as I have the desk pulled out feeding new coax and antennas into the shack...may not help much but will not hurt.

Going off topic a bit, I probably have a dozen UPS's in the house. I live in an area with quite a bit of power fluctuation and am moving to only replace the dead ones with mid range units with AVR, Automatic Voltage Regulation. Here, the older units have rarely lasted much beyond the first battery replacement and warranty, indicating that the the MOV's .....Metal Oxide Varistors are taking a beating and the higher end units are holding up better, using 1500 VA 900 watt replacements one by one. The computer UPS as they fail are being replaced by higher end true sine wave replication units due to the fact that the newer green power supplies for PC's will cause a lesser UPS unit to restart the PC rather than hold the power up until the battery switch is made if they do not see true sine wave going from a 75% efficient to 80 percent efficient green supply saves about a dollar a month vs $50-$100 premium for true sine wave replication on the UPS.....makes almost as much sense as green hard drives, which cost almost twice as much to run as a high performance drive, after running a week long test on one I bought.....never again....

I suppose we are lucky here in the UK with lightning, now rain we have a lot of. We had a house in our village about 5 years ago suffered a house fire through lightening strike but saying that my neighbour had fire caused by rats eating insulation off mains cables and catching fire in the loft (we are very rural). I have diecast box with SO-239 connections which is connected to my RF Earth via 6mm cable and just disconnect radio and connect all antennas/ATU's to the box. Just part of my operating routine but if I were living in Lightning central and had all those antennas etc. I might do similar. He must be retired and pretty well off though!

Just wondering if you people the other side of the pond have these "Old wifes tales" for when there is lightning?

put the forks away
turn mirrors around

Just being nosy

Wow, that's a great ground system. I did lightning protection work for the DoD for a while, and this amateur work matches anything I saw at DoD communications sites.

I lived in Miami for a year, and I know that he hasn't overdone it. The lightning activity there was amazing.

The problem that comes to mind is that most filters are designed to go the other way, that is, to protect the cable system from interference from the ham signals.

If the cable system uses 75-ohm coax, you might try hi-pass filters at the main distribution point, and possibly at each cable box connected to something. That might be a bunch of filters, but if it works, it would be worth it. Clamp-on ferrite beads on each coax coming out of a box might also help.

Good luck.

I have the MFJ-1700 B 6 radio, 6 antenna switch. I have not had any problems other than forgetting which antenna I’m on due to where I mounted the switch. The XYL said she did not want to see it.

On my FT-950 I have two antenna ports. My SB-200 amp is connected to port 1 and my tuner is connected to port 2. It seems to work very well. I’m in the process of making all the inside antenna cables to RG-8X.

From: pchapman920
Topic: 19719 Message: 19721

Hi Al:

No expert here but getting ready to do the same thing. I am using almost resonant antennas. I have used the Daiwa 201 for years to switch a Kenwood 820s and Icom 718 after coming out of an MFJ 949e tuner on a G5RV which is now defunct. With several new wire antennas going up, I bought an alpha delta ASC four antenna desk console. Without a tuner to fiddle with now, I'll take the output of the alpha delta as the input to the daiwa 201. I'll try it first on the Icom 718 before switching to my shiny new Icom 7410. HA!

One word of caution however and not trying to be critical by any means. Sometimes as you know, the QC at MFJ takes a day off. I read both good and bad reports on the 1701 as I considered it, but much preferred the Alpha Delta reputation and the gas fusing in the switch, as well as the built in ground buss bar. Most of the MFJ complaints were concerning leakage which could create issues in the arrangement. Check everything i.e. SWR on both switches and look for differences before proceeding. Even if everything is fine, and you have both rigs on tune the one not in use off a few KC from your operating freq to eliminate the possibility of birdies feedback, or at least hit the Attenuate switch.

Good luck with it!

19722. MA5B swr problems. (not soldering SS)

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-08 22:43:18 UTC
From: w9nfl
Topic: 19722 Message: 19722

I thought I would repost my original post. I'm hoping someone would have some advice.

I'm having swr problems with my MA5B and wonder if anyone has experience with this antenna. I've rechecked all my measurements and they seem correct. Even turned the traps around in case of them being labeled incorrectly.

Any help/comments are welcomed via this group or by my email.

Thanks, Keith W9NFL

Dale,

I have heard that the direction arrow on some traps might be wrong. Other than the matching network problem I haven't heard much other advice . This weekend I'm going to recheck everything (for the 100th time) and get the beam higher off the ground in case that might be part of the problem. When I mount it on my tower I want to add a small 6 meter beam 10ft above it. With all the issues I've been having not so sure I want to do that.

Thanks, Keith

19725. Question about RG316 coax

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-09 00:01:06 UTC
From: Benjamin Straw
Topic: 19725 Message: 19725

Does anyone have any experience with the use of RG316 coax in the mobile?
I'm planing on switching from a mag to a hatch mount and am looking at
coax. A friend told be that this type of coax has alot of line loss on 440.
I do alot of 440 qso's but its on a local repeater about 10 miles from my
qth and 18 from my work.
BTW I do plan on keeping my Tram 1180 dual band antenna.

I don’t think line loss is a problem with VHF or UHF but I could still be wrong. I’d just use it and see how it goes.

Topic: 19719 Message: 19727

Hi Al,
p_chap is right to emphasize checking. At the very minimum, check with an Ohmmeter. You can not depend on the manufacturer's good reputation in lieu of testing. Some years back I found a brand new Daiwa coax switch with paint overspray inside, preventing good switch contact.

If you pick up a used coax switch, particularly B&W, be aware that some models ground all terminals except the one selected, but some switches do not! The one by HeathKit was a good one. The only trouble I had with a MFJ switch was that it was very easy to melt when I tried to re solder the internals. Inspected, melted, and into the wastebasket in less than a minute.

For a long time I have used the following coax switching scheme to make selection and adjusting of HF radios and antenna systems quick and easy. It sounds complicated, but it makes a station with numerous radios and antennas much more flexible. Sketch it out and it will become obvious.

In this description, I use the word "common" to identify the coax socket that closes contacts internally with the selected coax socket in a multi position switch. This description does not address lightning protection or the connection of transmitter amplifiers.

One multiposition switch selects radios, (transceiver 1, transceiver 2, SWL receiver, guest radio) A second multiposition switch selects loads. (antenna coupler 1, antenna coupler 2, dummy load, reference antenna) The cable between the common of the radio selector switch and the common of the load selector switch passes through the inline SWR meter, which monitors the match between the selected radio and the selected load.

A third switch is a "tune/operate" selector with 2 positions: It determines whether you are tuning (adjusting the antenna coupler with help from a MFJ analyzer) or operating the selected radio. The 2 position switch is inserted between the inline SWR bridge and the common of the radio selector switch, with "operate" position connected to the radio selector switch. "Tune" position is connected to a MFJ SWR analyzer (which has only one coax connection). The common of the "tune/operate" switch is connected to the transmitter side of the in-line SWR meter.

In operation, you select a radio, select a load, turn the 2 position switch towards the MFJ analyzer, adjust the frequency of the analyzer until you hear it in the radio, adjust the antenna coupler until the MFJ analyzer shows a good match, turn the "tune/operate) switch to the operate position. There you are, tuned up and ready to ask "is this frequency in use?" without having trampled on anybody's QSO.

Before you declare this system to be an unsightly wire rat's nest, I will mention that the operator's view of the switching system can be as tidy as a cabinet front about 12 inches wide with 3 selector switch knobs on the front. I found it most convenient to label the positions of the selector switches with tiny colored self adhesive labels. Text on the labels is optional. Each knob position refers to a like-colored spot on the station's radio

shelf where the respective piece of equipment sits. If you change radios around often, the color dots are a time saver, as the identity of the shelf location is still blue as long as one radio has been swapped for a different radio.

Coaxial switches are available with fittings to accomodate mounting behind a panel. Use a box that is not very tall, but is deep enough that the front of the box is reachable from the operator's position and the outside surface of the back panel of the box where the switch is mounted is far enough back on the shelf to allow easy routing of coaxial cables. In my case I allowed the switches to hang over the back edge of the radio shelf for easy access in back of the station table. The shaft of the coax switch can be fitted with a shaft coupling and a long shaft extension which is routed through a bushing in the front wall of the box.

Sorry this post is long winded, but I wanted to share this method as long as switching was being discussed.

73,
Don WN9V

> problems using this configuration?

I don't think you system conforms to the KISS principle.
(Keep It Simple Stupid)

I would recommend assigning the "30m Radio Waze dipole" antenna to the FT-920 for 17 and 6 meter
(with the two position switch between the two outputs of the FT-920 if there are two outputs) work,
and everything else to the 6 position switch connected to the FT-1000MP.

When it is storming you will have TWO cables to disconnect, one on the back of each transceiver.

Can you find a friend (or your local HAM club) that has an antenna analyzer that you can use to
see if the bands are off frequency or gone? First find out what the problem actually is.

Ron Youvan is 100% correct. The source of the noise has not been identified, only the carrier.

Until the source has been located and the owner has been asked (and has failed) to remedy the situation, calling enforcement is a waste of time.

19732. Re: Question about RG316 coax

Yahoo group: ham-antennas (2011-08 — 2011-12)

From: David Zahler
Topic: 19725 Message: 19732

I think you may be painting yourself into a corner here by limiting the potential rage of your radio. While rg316 is great for interconnections between modules in a larger assembly, it really isn't suited for even a run found in a application such as yours. You will be losing almost half your power (2.6db) between the radio and antenna assuming a 15' run.

Take a gander at http://www.timesmicrowave.com/cgi-bin/calculate.pl to calculate the loss of the rg316 vs. rg8x. The loss of a comparable length of rg8x is 1.7db. While you give up some power handling capability, you get substantially lower insertion loss.

OK To start with it is Time Warner here in Ohio! The guy said I had a 100mv leakage and it was because of a loose connector on one of my boxes! It did nothing to fix the problem! My shack is grounded! i can walk into my front yard 15 feet from the house and the noise is GONE!
What do you mean by the carrier? I can walk over to the pole where the service comes to the house and it is nothing but hash from 150kcs to 30 mhz!
I am going to contact them again and see if I can get a better resolution!

Ok,

The Cable is suspect true?

Can you at the street level disconnect it? to see if in the house and
your station the noise level goes down?

If you can't do that, inside the house disconnect it as close to where
it enters the house as possible and see if there are any differences.

After that disconnection is made can you then pull the cable out from
there it comes through the wall, and take it as far away as possible
from the house and see if the levels change?

This should isolate it enough showing that the noise is coming from the
cable.

That still doesn't prove that the noise is originating from within the cable system, only that the cable wire is the carrier.

An arcing insulator on a nearby pole could be generating the noise, which is picked up and reradiated by the cable TV wire. Who fixes that, the cable company or the power company?

The noise might well originate from the cable system, but if it appears on the common mode, I doubt it.

The ARRL TVI/RFI book is a very useful resource.

I agree, BUT,

Their system is propagating the noise signal. So without their stuff
you wouldn't have the problem. So complain to them and they can
complain to the power company. but if their stuff is bringing in the
noise it IS their responsibility to make it stop.

What did the cable guy do to come up with his answer?

It sounds like the cable proper. There is probably an open shield
somewhere. If the pix is good, then the center conductor is probably ok.

You should not be getting that kind of noise from the cable setup.

I can't do that as it is in a locked box! i they find the box tampered with they disconnect your service! I took a small portable SWL radio(Eton E5) to the outside to where the cable comes into the house and the bands were nothing but RF hash!

Don, I would like to jump in please and say I think your approach is great!
I will look into this arrangement for my multi radio... multi antenna set up
this fall.

Thanks again,
John

Here in something to think about , 2 years ago my cable went out the cable guy came over and replaces a bad splitter box under the house , i have cable in every room of the house (not the bathroom) well he checks the system and asked how my picture was before i lost the picture , i said it was ok. then he asked how many years i have had this same cable , i said about 10 years or so. he then said the guy that installed this cable never hooked up the ground .Well to make a long story short . I have never had a noise problem in eather my old Kenwood 820 or my Ten Tec Jupiter. ???

Hi Guys

I'm thinking of building a remote antenna switch using relays to switch 6 antennas to 4 radios. All antennas are resonant but the swr might approach 3:1 at band edges.
As I would like to run an amplifier at 400 watts my question is how much current and voltage would the relays need to handle to cope with these values. I have been thinking of using mains contactor's with a 10 amp rating dpdt.

Thanks in advance

Eddie

Hi Eddie

I think you should be able to calculate by just using Ohms law and derived power formula. so current is derived from power equals current squared multiplied by resistance. Now the resistance or more correctly Impedance for a 3:1 SWR is a maximum of 150 ohms and minimum of 16.66 ohms so working backwards

I=1.6A to a maximum of 4.9A

similarly with Voltage from power equals Voltage squared divided by Impedance

V= 244v to a ninimum of 81.63v

Now these will be RMS figures so bear that in mind when looking at ratings, I would also use 2 relays for each line (inner and outer of coax) reducing the capacitive effects between them.

Thinking of the power supply to the relays I would go for centre tapped transformer with the centre tap earthed and bi-phase rectfication with decoupling capacitors at the feed and relay positions. Probably something like cat 6 cable supplying rather than the unscreened cat 5e type.

Presumably you will have some form of interlocking? I seem to remember that the guy I got my LC meter from does something that may be useful he is at www.s9plus.com called "TROPIC" his is PIC based.

hope this helps and even more importantly I have got the maths right.

thanks for all the replies they have been very helpful.

In answer to you question i am running the following antennas

a3s and a3ws 30m and 40m parallel dipoles a fullwave 80m loop
and an inverted L for topband .

These are all fed seperately which when combined with 6m,2m and 70cm yagis and a 20m colinear means i have alot of feeders coming into the shack and at the moment no easy way to switch the hf stuff to the radios.
I'm using 2 3way antenna switches but they are marginal in power handling plus it would remove 5 feeders from the shack.

thanks again

Eddie

19747. My antenna dilemma...

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-10 23:26:48 UTC
From: neilkj6fba
Topic: 19747 Message: 19747

My current ham activities are limited to 2 meters and 440 and the discone I currently have serves nicely for my UHF / VHF ham radio and for my scanner.

I will be testing for my general license in two weeks and am interested in having an antenna for use in PSK-31 activities (mainly 14.070 mHz). There are some serious restrictions in my homeowners association about antennas "clearly visible from the street".

I could erect a SLIM vertical antenna - maybe extending about 5-8 feet above my roof line. I could also use the random wire (about 100 feet long) that I have routed along the top edge of my wooden fence. I get excellent reception of ham traffic (including PSK-31) using that antenna.

Now the question is: could I adequately load a vertical antenna with no radials at all or load my fence wire antenna with a reasonably priced tuner? For the vertical I could certainly drop a single counterpoise wire of maybe 12-15 feet straight down. Obviously the PSK-31 transmissions would be very low power, perhaps 10 - 20 watts. Yagis or extensive radials are out of the question. I suppose I could run a dipole along the fence but it would be only 5 feet above ground, present impedance issues,and possible receive poorly off the ends. Any HF rig I buy will probably have an SWR meter included. It might even include VHF/UHF with dual antenna inputs!.

Advice or comments sought and eagerly accepted!!

I was a Novice for 17 3/4 years and I had HF privileges the entire time.

If anyone can touch the antenna (or get very close to it) is it not permitted to apply very much
power, you should have learned about health and safety with respect to RF power in your `general'
studies.

If your HF and VHF/UHF radios are separate the VHF/UHF can operated muted (squelch) while you are
operating the HF radio.

> Advice or comments sought and eagerly accepted!!

I don't understand what a vertical's radials have to do with it being a stealth antenna. The
radials should be buried under the turf. The vertical also needs to be not touchable by family and
strangers.

HAM sticks, HAM sticks dipoles, out-backer, loops and other loaded antennas can be used to provide not-obvious antennas for HAM use. If you have a back yard you most likely have it made.
Unfortunately antenna performance is a reflection of it's height. (up in the trees can be great)
GL on your upgrade.

A ground mounted vertical antenna works fine on 20m. An aluminum flagpole that's about 3/8 wavelengths long on 20m - about 25 feet - makes an antenna that doesn't look like an antenna and, with a bit of loading, can easily be made resonant on both 20m and 40m. 3/8 wl on 20m will give you about 50-60 ohms of radiation resistance, which will help with efficiency if you can't lay down a perfect radial field.

If you use fiberglass or some other insulating material for the pole, it's possible to build a 6 or more band antenna system INSIDE the flagpole. There are also manufacturers of such antennas.

Forget vertical antennas (except a vertical dipole) if you can't lay down radials. The difficulty in doing so is vastly overrated. Lay them on top of the lawn now and they'll have disappeared into the thatch by the first mowing next spring.

Make the vertical 12-12.5m
With a series coil this is a real 5/8 vertical (impedance close to 50 ohms!)
With some low angle gain
And with a series cap you have a bit over 1/4 wl vertical for 40
That magic length will give you 2 bands in one antenna with easy matching
(only one part per band) and both show close to 50 ohms
A 3/8 wl antenna will have higher impedance (close to 100 ohms) ... that is
why the hf6v and hf9v use a quarterwave length of 75 ohms coax for
transforming on 20m
Dg9bfc
Sigi
Ps a slightly different cap and you can use it also on 30m :-)

You r so rite Jon. Both my tri band and 40meter beams are down for repairs. I built a full wave 80m loop which is cross-polarized for high and low angle and In last 3 months have tore up 20/40/80. I love it. Boy is it quiet. From Tn working JA's also Eur. 279' of 12 stranded. In a triangle shape with the top apex at 50' on my tower. Then pull the bottom corners out until each corner is at the 6' level and the back 93' is 6' across to other corner. Of course you pull as tight as you can. I feed mine at the corner with 450 ohm ladder line for 150' to 4:1 balun to another 9913 coax run of 129' to shack. I don't use the tuner on my ft950 that much. Very broad banded. ARRL (More Wire Antenna classics volume 2, page 4-4 to4-6, Chap 4. I've made a few ants in my 41 yrs as Ham, But in all reality, it shouldn't work this well. Most all came from my junk box except the wire. Wire is not cheap. Build it and let me know. Roger Hughes, W4IV PS: I don't own an amp. I would like to though. Hi HI 73, There is at least 17 been built and own the air in the Tn-Ky area.

I put a fan dipole in the attic: 40/15, 30, and 20. I had to bend the 40 meter element at the ends, making a "Z" shape. It worked acceptably, and I was able to work some DX with it. It's not great, but it's better than permanent QRT.

But an 8m whip with 4.5m wire to next tree maybe?!?
Or the whole antenna only made from wire ... support line from house to tree holds the wire vertical ... that would be more stealthy

19756. Radials Crossing

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-13 01:19:21 UTC
From: Jay
Topic: 19756 Message: 19756

Hi,

I replaced my Butternut vertical with a new DX engineering 43ft. I have 32 radials about 25 ft and want to add more for the DXE, maybe another 20 +/- 40-50 ft ones. My problem is at least half of the radials around the antenna have disappeared in the lawn the other half are visible because there is no lawn in that area just dirt. In the half hidden that is hidden if I lay down more they are more than likely going to cross the ones that are there. How will this affect their performance etc if they cross.

Will I gain much by doing this.

Thanks Jay N1FDX

19757. 40 meter dipole vs G5RV?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-13 01:43:52 UTC
From: pchapman920
Topic: 19757 Message: 19757

Been switching my old rig, Icom 718 back and forth to my Icom 7410, and only have memory to work with as the G5RV is gone and the dipole is the first of several going up. (with a balun to help keep RF out of the office, and that point is working way better.) So far I am finding the plain old dipole much more quiet on the band than I remember, not picking up power line or other noise, and of course as would be expected performing better as a single band antenna, way better than I expected.

The G5RV was a van Gordon sold by HRO, and I talked around the world with it. Just seems as though there was a higher noise factor overall on all HF bands to deal with. Everything going up, by my own rule, will be close to resonant, to be handled by an internal ATU for tweaking only.

Comments, or similar experience?

From: Ray Kasprzak
Topic: 19756 Message: 19758

I had roughly the same scenario. I had 22 radials that disappeared into the grass. I purchased the radial plate and added 28 more. I am sure that several probably ended up crossing. I have not noticed any detrimental effects and the characteristic impedance has if anything slightly improved. Over reliable propagation paths my signal improved by six db.

> Will I gain much by doing this.

Crossing is no problem. It will decrease your resistive losses, in creasing your efficiency.
The characteristic impedance of the vertical antenna should be lowered by the reduction of series
resistance.

Has anyone used a hustler mobile or similar as a portable antenna with radials laid out?
Would this work as opposed to a mp-1 or similar portable antennas.
I used the hustler with the triple tree so three bands instead of just one at a time.
Thoughts?

Thanks

I use an Opek HVT400 as a portable antenna. I have it attached with a trunklid mount to a 4 inch square of steel, with a bunch of random length radials. Works ok when clamped to a picnic table, not the best antenna i the world, but it does the job.

I used a KJ7U kilowatt model in a semi-fixed configuration with 20 radials. It worked OK. I worked 24 states in about an hour during a 160 meter contest, and it loaded up on all bands from 160 to 2. I sneaked it out into the yard after dark at a QTH where the HOA prohibited outdoor antennas.

From: kd8dvy@ymail.com
Topic: 19757 Message: 19763

You have to remember that the noise was not coming from the radiator part of the G5RV it was coming from the twin-lead feed-line. I had the same problem with a homebrew G5RV and then I made a Doublet and it is more quieter than the G5RV because the twin-lead is not acting as part of the receive. Don't ask why it just is.

Also the twin-lead was and used as receive antenna for the analog radio waves that we still have around.

I have been cutting, tweeking, tweeking some more, and cutting even more and now have my 75/80 meter dipole "respectfully"ressonent about 3550 which I can tolarate for cw. My original inion was 3800~. Keeping the antenna intact (no more cutting) will the ends "fold back upon themselves when I want to operate in the DX ssb window without major issues?

I am using 12 gauge thnn attached about 30' up on my tower with a pully and each end spread about 45* to just off the ground. I am using a MFJ 962C tuner and 100 watts. Feeding with coax run of about 60-70'. I am a little afraid of using the internal tuner on my Kenwood, but may be being a little over to causaus.

Any thouoghts

19766. "Cheap Yagis"

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-14 01:16:33 UTC
From: hitekgearhead
Topic: 19766 Message: 19766

I have seen the websites/pdfs showing how to construct cheap yagi antennas with a half folded dipole driven element so that it can be directly fed with 50ohm coax.

The designs look quite simple and I think I will build one for 2m.

I would also like to build one centered on the GMRS frequencies, but there in lies my problem.

The common dimensions listed on the chart for the 70cm antenna give figures for an antenna centered around 432MHz. There are also dimensions given for a 450MHz version.

I need to scale the antenna for 462MHz but don't really know how to go about that.

I was wondering if you guys might offer a little assistance.

Thanks,
Albert

I'm guessing you are asking if you can pull more copper through the end insulator and wrap it back on itself to increase the freq resonance. I talked to an antenna guy I bought a unit from a couple weeks ago, as it was designed to use as an inverted v and not horizontal as it has to be installed. I did not ask enough questions, but he did tell me to shorten the antenna regardless of band and do a wrap back of an extra 4 inches to each side prior to hanging....add or subtract to find resonance from that point......and leave it for later if needed. I failed to ask him about long term as bare stranded wire undergoes serious oxidation over time. In my case, as what I bought were budget antennas, I am going to tweak and solder. Give it a try....you will probably be OK

From: pchapman920
Topic: 19757 Message: 19768

Sounds logical....just so many reasons I am going back to simple stuff that is pretty well resonate with the one exception....the MYSTERY W5GI which is going up soon which uses twin lead and a 75 ohm stub to make it quite resonate on 20....I had to check it out....too much curiosity.....

--- In ham-antennas@yahoogroups.com, "kd8dvy@..." <kd8dvy@...> wrote:
>
> You have to remember that the noise was not coming from the radiator part of the G5RV it was coming from the twin-lead feed-line. I had the same problem with a homebrew G5RV and then I made a Doublet and it is more quieter than the G5RV because the twin-lead is not acting as part of the receive. Don't ask why it just is.
>
> Also the twin-lead was and used as receive antenna for the analog radio waves that we still have around.

> >
> > Been switching my old rig, Icom 718 back and forth to my Icom 7410, and only have memory to work with as the G5RV is gone and the dipole is the first of several going up. (with a balun to help keep RF out of the office, and that point is working way better.) So far I am finding the plain old dipole much more quiet on the band than I remember, not picking up power line or other noise, and of course as would be expected performing better as a single band antenna, way better than I expected.
> >
> > The G5RV was a van Gordon sold by HRO, and I talked around the world with it. Just seems as though there was a higher noise factor overall on all HF bands to deal with. Everything going up, by my own rule, will be close to resonant, to be handled by an internal ATU for tweaking only.

you are saying pretty much what i was thinking. However, since I am fairly resonant on the cw (longer) end, I am thinking that when I want to operate DX phone, I should be able to take the (insulated) wire and wrap it's self around to make it shorted for the phone band, without cutting. Am I on the right track?

Yes that works ... we do he same thing on fieldday with our inverted v antenna ....(and I do on my resonant radials) lower ends, fold back and use it on phone ...
Lower it again, unwrap and let the end tangle down to lower resonant spot to cw end ... so you can let the insulator attached to the shorter point and let a pigtail tangle down from that .. wrap around to give you the phone or dx portion (3.6, 3.7, whatever)
So ... yes it works ... no need to solder it

I always cut each half of my dipoles 6 feet to long, I run the end back through the end insulator
coming back 3 or 4 feet the I secure the end with a small "split bolt." I test and loosen and slide
the end back or fourth with the "split bolt" and wire end back or fourth as required.
I bend about an inch of the end of the wire back at 90 degrees just past the "split bolt."

Yes Dale you are on the "right track", I've been using dipoles for years and I still haven't learned how to cut them the right length. On 160 or 80 I always cut the antenna a couple of feet long and then just fold the excess back onto itself with a twist or two.

If I feel like it, I will trim the excess off when I'm done tuning, but I've learned to not get into a big hurry with the trimming part, use the antenna a few days or weeks before cutting the excess wire off. I always end up tinkering with the antenna for a few weeks before I chop off any extra wire.

I usually use a couple of cable ties to keep the excess wire from unwinding until I decide to cut it.

And yes, I've used your strategy many times over the years, good luck with your project Dale.

Trying to recycle as much as possible.....why waste money and throw stuff away that can be reused anyway?

Have 50 or sixty feet of RG8X that was part of my old G5RV, just enough feed line for one of my double bazookas going up. 259's already done so I will find out more later, but have a couple of questions. I cut off a foot or so from where the outside connection was made and it was the same as where I cut it only a few inches. The braiding was blackened, and I thought that might be from aging jacket bleed. It cleaned up ok, although the coating was a little heavy. The jacket itself is still in decent condition with no cracking or loss of flexibility.....about eight years old.....and most decent RG8X is rated 12-15 years. To my surprise, the inner conductor was very much the same....blackened and took a bit of effort to clean up. In examining the dielectric (around the center stranding conductor), it seemed to be fine....no discoloring, still soft, not brittle at all, and ohming out both conductors a near perfect zero on two decent, one an (very) old high end Mura Analog and the other a new higher end (within the brand) Amprobe DMM,(owned by Fluke) although not Fluke brand meters.

I'm sure the proof will come when I get the antenna up and see the SWR as a go or no go, but wondered what others have experienced when using older coax, if it is pretty much the same with the blackening when all of the physical characteristics are still in decent shape?

Thanks,
Paul WA4NUN

19776. heliax for mobile

Yahoo group: ham-antennas (2011-08 — 2011-12)

From: hitekgearhead
Topic: 19776 Message: 19776

I was just wondering if the smaller superflex types of heliax would be appropriate at all for mobile applications? Anyone ever try it?

I know you might say WHY?... being as the cable run might be only 20 ft, and if I used something like LMR-240 ultraflex I would have pretty minimal loss even at the upper end of UHF.

So... just for argument sake, lets say there is just some lying in the back of my ham shack closet.

Thoughts, ideas, arguments?.....

19777. peltaway antenna

Hi all
I have found this website http://deepfriedneon.com/tesla_f_calcspiral.html it calculates the inductance of a spiral of conductor in a flat plane so if you fancy making peltaway or spiral antenna may be of use. Being really sad I was thinking about how to calculate length of a spiral on a cone. I was thinking of using a fishing pole and putting window alarm tape as a spiral up it and how to work out pole dimensions etc.
My reasoning was that the tape is 1/4" wide so should be quite broadband compared to wire and would not break the bank as "something to play with" to make a 3/8 wave vertical or similar for 20m. I do have some mad ideas just before I fall asleep.
Any thoughts? not a mathematician myself.

I'm sorry but the coax is bad, if it's black inside that means water/moisture got inside and is no-longer good. I would recommend replacing the whole coax.

I cut off a foot or so from where the outside connection was made and it was the same as where I cut it only a few inches. The braiding was blackened, and I thought that might be from aging jacket bleed. It cleaned up ok, although the coating was a little heavy. The jacket itself is still in decent condition with no cracking or loss of flexibility.....about eight years old.....and most decent RG8X is rated 12-15 years. To my surprise, the inner conductor was very much the same....blackened and took a bit of effort to clean up. In examining the dielectric (around the center stranding conductor), it seemed to be fine....no discoloring, still soft, not brittle at all, and ohming out both conductors a near perfect zero on two decent, one an (very) old high end Mura Analog and the other a new higher end (within the brand) Amprobe DMM,(owned by Fluke) although not Fluke brand meters.
>
> I'm sure the proof will come when I get the antenna up and see the SWR as a go or no go, but wondered what others have experienced when using older coax, if it is pretty much the same with the blackening when all of the physical characteristics are still in decent shape?

From: Siegfried Jackstien
Topic: 19764 Message: 19779

Let the ends a bit longer as needed for cw (do not cut more)
If you erect the aerial higher the esonant point will go up (less capacitance to ground) and you would have to add wire to the ends if cut too short ...
And here explanation WHY this works:
On the end of the dipole you have almost no current but high voltage
And that is why the wrapped end couple so strong to the inner part

Now if you wrap the ends around to shorten it the end becomes "invisible" for the rf cause the inner part (the long leg) and the outer wrapped around end couple together as they were a bit thicker radiator

We also did this on a fieldday with a vertical antenna to change from one band to another
We erected a 10m vertical with a top-hat wire to make it resonant on 80 (Upper and outer or inverted l)
With loosing the guy line and let the end down to the pole the resonance raised from 80m band to 40m band (but that was a LONG end to make invisible)
So ... yes definitively it works :-)

19780. Re: [ham-antennas] "Cheap Yagis"

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-14 12:29:47 UTC
From: Frank Kirschner
Topic: 19766 Message: 19780

L(desired) X F(desired) = L(given) X F(given)

where L(desired) and F(desired) are the length and frequency you want, respectively, and L(given) and F(given) are the numbers given in the chart. So

L(desired) = L(given) X F(given) / F(desired)

Units don't matter as long as they are consistent.

This formula will work over a considerable range, as long as you don't change the ratio of the length to diameter of the elements so much that the velocity factor changes.

I have never heard of this, but I have heard of two related schemes.
I have seen an egg insulator with a removable shorting jumper wire. (with a small battery clip)
This was on an inverted "V" at field day. It took 30 seconds to change bands.

I have read about going out 3/4 the way to the end of the dipole and add (with a split bolt)
another wire that drops straight down to add a higher frequency band or to broaden one band. I have
not tried this method. Remember for health and safety no one should be able to reach up and touch
the wire ends.

The only problem with the use of superflex helax is it's intolerance to repeated flexing. Incidentally 1/4" superflex has greater power handling capacity and lower loss than RG-214/U coax.

If your primary mode is Phone, I'd cut it to be the best where you
mostly operate. Then Like we do on Field Day here we have "Stubs" where
all they are is an alligator clip and the extra length of needed wire to
drag it down to the bottom portions of the band. One on each ens and we
just clip it to the ends and done.

19784. Re: [ham-antennas] "Cheap Yagis"

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-14 14:56:57 UTC
From: Joe
Topic: 19766 Message: 19784

Seems ya got it backwards.

But anyway yes scaling EVERYTHING does get you soo close you won't know
the difference.

so lets try this as an example. you have an antenna that is made for
435MHz and you want to scale it to 470 MHz simple.

So say the element length of the existing antenna is 12 inches,

the formula works out

12 times 435, divided by 470 equals 11.106 inches long
element diameter is 1/8 " 0.125

0.125 times 435 divided by 470 equals 0.115" diameter

Just scale everything and it will work.

Trying not to open a can of worms, but as you bring it to resonate, are you trimming to produce a 50ohm match or a low VSWR match?

One school of thought goes for setting up aerials to produce a 50 Ohm match (zero Xl/Xc) the other school which we mostly go for is to trim for a min VSWR @ Tx where you want to operate.

You are probably right. I can only hope that you are wrong. I've already done the connections and assembly. I was waiting on help to get the all band antenna over the house and take the 20 meter bazooka with it, but think now Ill just hoist the bazooka for a test drive, so if I have to order more coax I'll know before going through a lot of trouble twice. Getting an antenna over a house with architect style shingles is a pain cuz they grab everything that hits.

You are trimming for resonance more than anything . as long as you get it below 1 5 to 1 most modern transceivers can handle it . my dual band 20/40 metre dipole is resonant with a 1.3 to 1 SWR at 7237.5 khz and 14227.5 khz and the measured resistance with a MFJ analyser is 30 ohms . The FT 950 is quite happy with it without the internal tuner . the swr does go up a bit at the band edges but is not out of range of the internal tuner .

If you got it use it as its free. Nobody wants to argue. You being the person who makes the final decision always it matters not what you use. I myself use a diamond VHF/UHF antenna. The coax is not as long as I wanted so I put a 6’ piece of LMR 400 ultraflex on the end of my coax. Seems to work just great. I’m of the opinion that when doing FM VHF/UHF it matters not what you use at all. I would use LMR 400 ultraflex from the antenna to the radio for the lowest line loss but that is not practical. For my home shack I will be using LMR 400 from antenna to the switch and from the switch I use LMR 400 ultraflex.

just my $0.02

Enjoy

Subject: [ham-antennas] heliax for mobile

I was just wondering if the smaller superflex types of heliax would be appropriate at all for mobile applications? Anyone ever try it?

I know you might say WHY?... being as the cable run might be only 20 ft, and if I used something like LMR-240 ultraflex I would have pretty minimal loss even at the upper end of UHF.

So... just for argument sake, lets say there is just some lying in the back of my ham shack closet.

Thoughts, ideas, arguments?.....

Subject: [ham-antennas] Re: Aging coax question, a different one

You are probably right. I can only hope that you are wrong. I've already done the connections and assembly. I was waiting on help to get the all band antenna over the house and take the 20 meter bazooka with it, but think now Ill just hoist the bazooka for a test drive, so if I have to order more coax I'll know before going through a lot of trouble twice. Getting an antenna over a house with architect style shingles is a pain cuz they grab everything that hits.

Siegfried what is a top hat wire. I have an A-99 10 meter antenna. I would be very much interested in learning how to also do 80 meters with it. The antenna base is up about 20 ft off the ground and the bottom of the pole is up 2250 ft.

Let the ends a bit longer as needed for cw (do not cut more)
If you erect the aerial higher the esonant point will go up (less capacitance to ground) and you would have to add wire to the ends if cut too short ...
And here explanation WHY this works:
On the end of the dipole you have almost no current but high voltage
And that is why the wrapped end couple so strong to the inner part

Now if you wrap the ends around to shorten it the end becomes "invisible" for the rf cause the inner part (the long leg) and the outer wrapped around end couple together as they were a bit thicker radiator

We also did this on a fieldday with a vertical antenna to change from one band to another
We erected a 10m vertical with a top-hat wire to make it resonant on 80 (Upper and outer or inverted l)
With loosing the guy line and let the end down to the pole the resonance raised from 80m band to 40m band (but that was a LONG end to make invisible)
So ... yes definitively it works :-)

19792. Phillystran 1200 and pulleys ???

Yahoo group: ham-antennas (2011-08 — 2011-12)

Question... I have decided to invest in "lifetime" support lines for my Cobra and have purchased Phillystran 1200 -- I always suspend my lines and wire with pulleys but looking at this stuff, with its shiny plastic cover, I am not sure what size/brand of blocks I should use for this installation.

Any suggestions?

thanks

Our dipole for fieldday is cut for cw part ... but I am no code operater ...
I like to use the antenna higher ... so I just let the ends down (THAT ARE
LOW TO EARTH ANYWAY) ... and wrap the ends around ... so my ham-friends in
the club can still use it later on cw again ...

Dale if the ends of the dipole are easy to get it why not do it this way. Make it resonate in the DX window. Then add wire to it when you want to go down to the CW portion of the band. With 100 watts you could clip the added wire on and off when needed. Put an insulator on each add on section and have a small piece of rope off the insulator to the clip. Then just clip that on to your support rope when you have to.

Remember this, if the ends of the antenna are low to the ground the SWR will be effected by snow underneath it. I have seen the resonate point on my 40 meter dipole move in the winter due to the 3 feet of snow below the one end of the dipole. And that end was 10 feet off the ground before it snowed!

I talked to an antenna guy I bought a unit from a couple weeks ago, as it was designed to use as an inverted v and not horizontal as it has to be installed. I did not ask enough questions, but he did tell me to shorten the antenna regardless of band and do a wrap back of an extra 4 inches to each side prior to hanging....add or subtract to find resonance from that point.....and leave it for later if needed. I failed to ask him about long term as bare stranded wire undergoes serious oxidation over time. In my case, as what I bought were budget antennas, I am going to tweak and solder. Give it a try....you will probably be OK

I use the LDG 200AT Pro tuner and I have tuned it for 12, 15, 17 and 20 meters. It's a great antenna and no ground radials to speak of. I have 3 short radials attached to the base of the antenna. I talked to Australia one day with it on 28.455. I live in California. I'm probably about 200 miles or so from the Pacific Ocean.

My 80 meter dipole was put up when I was a general so my Linear doesn't' tune well down in the Extra portion of the band so I'll probably have to lengthen the antenna so I can use my SB-200 amp at 3.6 and up.

I have a video of a ham (OH2BH) in Finland who made a 80M beam for CW. It was very impressive.

http://www.radioarcala.com/nbspStation/16080MMammothBeam/tabid/380/Default.aspx

It's a fun video to watch every now and again. For a year or so he lived about 40 miles from me in the big city of Madera, CA

We had a demo of a 80/75 / 40 meter NVIS dipole. One thing he had was a spade lug M / F. When he wanted to go from 40 to 75 meters he just connected the spade lugs together. That is another nice way to connect your wire.

Dale if the ends of the dipole are easy to get it why not do it this way. Make it resonate in the DX window. Then add wire to it when you want to go down to the CW portion of the band. With 100 watts you could clip the added wire on and off when needed. Put an insulator on each add on section and have a small piece of rope off the insulator to the clip. Then just clip that on to your support rope when you have to.

Remember this, if the ends of the antenna are low to the ground the SWR will be effected by snow underneath it. I have seen the resonate point on my 40 meter dipole move in the winter due to the 3 feet of snow below the one end of the dipole. And that end was 10 feet off the ground before it snowed!

I talked to an antenna guy I bought a unit from a couple weeks ago, as it was designed to use as an inverted v and not horizontal as it has to be installed. I did not ask enough questions, but he did tell me to shorten the antenna regardless of band and do a wrap back of an extra 4 inches to each side prior to hanging....add or subtract to find resonance from that point.....and leave it for later if needed. I failed to ask him about long term as bare stranded wire undergoes serious oxidation over time. In my case, as what I bought were budget antennas, I am going to tweak and solder. Give it a try....you will probably be OK

Chas,
Harken makes some really nice blocks in a huge variety of sizes and styles.

You can get to their website by doing a search on harkenstore.

I have used the micro block 224 on Dacron and Nylon lines with no visible wear after years in the trees. Also used their bullet blocks. Take your time with their catalog and data sheets. You might try their phone number for tech advise to be sure that you have just the right model for your application. I would be sure to verify with the Phillystran manufacturer that the product can be flexed and run thrugh a block. Never heard of Phillystran being run through a block, but I am sure the manufacturer of the line knows about thimbles, terminations, flexing, loading, and minimum radius.

Be sure to take some pictures to show us what a first class installation looks like.

Dale, fire that internal tuner up. If it can't tune it, It will stop. There are several options on having the top and bottom freqs usable. A double Bazooka cut for 3650 should get you to both. Thats what so cool about Bazookas is the bandwidth. Fine some old small coax. Abt 70' plus. Last one I did I used rg58. 20'-30' of 450 ohm ladder line. I believe later on I changed ladder line to 12awg insulated wire. I used it in the 75m DX window plus CW area.

Back to ur dipole Dale. I built a OCF last year, but I just don't like it and It don't like me. It's a 45'/90' w/4:1 balun. It is coming down. Putting back up my cloud warmer. 132', 12 awg stranded insulated and fed with 60'-70 ' of 300 ohm ladder line. I love to use ladder line. So easy to tune tuner. Trying to get set up for winter and some contesting. I got th7dxx triband beam on one tower broke. Hygain 7-3, 3 element 40m beam for other tower but still on the ground. A wild storm broke the suicide bolt on the tailtwister rotor. So beam was loo se and yanked my jumper coax right out of the balun. Of course the balun exploded into several pieces. That was my tribander. Plenty of work here to do. I.m on disability as heart transplant abt 15 years ago. I can't get my wife to climb. Something about kissing something. Anyway a full wave loop is a great ant. I have one in triangle shape. I work plenty of barefoot DX. My next ant will be a 4-square for 75/80. I don't have much money so I scrounge for wire and other parts. I find a lot of ant stuff at the metal yard where they buy from you by the pound. . I better go Dale. Drive on. 73, Roger, W4IV< south of Nashville, Tn

all is well.....though when using hte tuner the output goes down as the tuner makes a better match. i can have a 1.5 to 1 and have 20 w output or i can use the tuner (external) and bring tthe power up near 100w with external tuner. i am sure there is a mis=match somewhere but i would rather tune for max smoke

My main concern was from the vibration of mobile use.

The mount would be placed in a location that there would not be repeated flexing of the cable. (No trunk lid mounts)

Thanks everyone for the input.

A lot of people do things that way all of the time, we all do it that way sometimes, but for best
performance we frequently try to get the antenna "right." It is the single most important improvement that we our self can make to our station, beside QRO.

There are no mysteries associated with antennas, but there are unseen forces everywhere that
effect many of our antennas that frequently mystify us, but there is no magic or secrets.

We know that any loading or traps enable us to do tricks at the expense of antenna bandwidth.

We know that quarter wave length vertical antennas need a counterpoise (also called radials) and
that dirt makes a very lossy counterpoise, (water is not bad) the antenna with a very good counterpoise has a load impedance of about 35 Ohms, but with dirt as it's counterpoise nearly 50
Ohms is easily reached.
We know replacing the dirt with metal (by adding radials) the impedance will eventually reach 35
Ohms, making it a worse match to the 50 Ohm coax, while improving its "radiation resistance."
(the amount of that 35 Ohms that will be radiated, it's efficiency)

We know that with just about any horizontally mounted antenna, the reflective surface under the
ground reflects energy back to the antenna based on the round trip distance, and this returning
energy alters the impedance of the antenna. (up or down) This also applies to beam antennas made
from dipoles.

We know that a vertically orientated half wave length antenna fed at the bottom is called a dipole, and that it needs NO counterpoise. If it is fed with an open ended quarter wave length
matching stub we get to call it a "J" pole.

We know the center of dipoles have a load impedance of about 73 Ohms in free space, when not
altered by reflections or other objects. We know when objects are near the antenna, objects like
houses, barns, cars and dirt the capacity between the objects and the antennas lowers the natural
resonant frequency of the antenna, so we must shorten the antenna to keep it on the frequency that
we selected. We know if we feed a dipole off center we get to do some unusual things with them.
We now we can buy 75 Ohm coax where we buy 50 Ohm coax. (in several sizes)

We know the wire of a dipole is the inductor and the tips of the wires of the dipole make up a
capacitor, the two are in parallel so we have a resonant circuit, just like the tank coil and plate
capacitor of a tuned circuit connected to the plate of an 807 or 6146. We know anything that gets
near the ends changes the capacity, changing the tuning of the resonant circuit.
We know if the antenna is off tune because of nearby objects we must change the amount of wire to
return it to being tuned on the frequency that we selected.
We know we can precorrect the phase of the energy going to the antenna (with an antenna tuner) so it
works better, we even need to do this at some band edges.
We know if the antenna wire is real slack and the winds blow it back and fourth as storms sometimes
do, the tuning will change so we keep them reasonably taught with pulleys and weights.

From: fred
Topic: 19805 Message: 19805

I need to be able to shorten the one I have (120 ' + -) to be able to get it in the available space , could I make it into a folded dipole and will that cause more problems than it solves ? I did look on the internet for ideas and did find lots of information but not being an engineer most of it was well beyond my ability to understand .
any thoughts or ideas will be welcome .
tnx

I have an Alpha Delta DX-LB dipole for 160, 80 and 40 meters. Not using it any longer. 100 ft long. Looking for a buyer if anyone is interested, email me at dan-schaaf@...

A couple things come to mind. What frequency are you trying for? How much height do you have to work with? You can make an inverted V fan dipole and be sure to keep the ends out of hand reach. You can also put up a nice loop around the property.

I say this sitting on 8 acres.

3900 Khz
due to my location 3 blks away from the EMS helipad I am limited to a 35 ft height . don't know why as the trees are taller than that .
the problem is that I have one tree in the front and the chain fence in the back . the tree is 53 ft from the pole and the fence is 85 ft from the pole , I considered building the OCF but it is too long for the back yard section . The dipole I have works well , I just have to tie it to the speed limit sign in the front as it extends past the tree , if I forget to take it down when finished using it I will find it on the ground in the morning . guess the city is cutting it down . am asking if I can turn it into a folded dipole without causing a lot of problems . a loop is not possible here , not enough support points . there is a pine tree on the north side and 3 pecan trees on the south side , nothing in the front or back yards . am in the city on a corner lot . is long and narrow .

Ha ha, I guess I should have just looked at the subject instead of asking what frequency.

I have never made a magnetic loop but this page talks about one for 40/80 meters.
http://www.standpipe.com/w2bri/

Might be one way to get past a small lot. Sorry I can’t help more.

How many meter are you too shor in space?!? ... just bend the ends to
another support (tree, garage, speedsign, whatever) ...
The most radiation will come from the current-point in the air
It will not hurt bending the ends

There comes a point where you get so little improvement for too much work! 1/4in Superflex would be great if your cable run is 30ft or so..for the normal 15-17 foot max run of coax in a mobile installation, your normal RG58 supplied with the NMO mounts is fine...IF you run HIpower (more than 200watts) or have a LONG run of cable (30+ feet), then I would suggest SF 1/2in...but for normal use? naw...aint worth the trouble

If you got it use it as its free. Nobody wants to argue. You being the person who makes the final decision always it matters not what you use. I myself use a diamond VHF/UHF antenna. The coax is not as long as I wanted so I put a 6' piece of LMR 400 ultraflex on the end of my coax. Seems to work just great. I'm of the opinion that when doing FM VHF/UHF it matters not what you use at all. I would use LMR 400 ultraflex from the antenna to the radio for the lowest line loss but that is not practical. For my home shack I will be using LMR 400 from antenna to the switch and from the switch I use LMR 400 ultraflex.

just my $0.02

Enjoy

Subject: [ham-antennas] heliax for mobile

I was just wondering if the smaller superflex types of heliax would be appropriate at all for mobile applications? Anyone ever try it?

I know you might say WHY?... being as the cable run might be only 20 ft, and if I used something like LMR-240 ultraflex I would have pretty minimal loss even at the upper end of UHF.

So... just for argument sake, lets say there is just some lying in the back of my ham shack closet.

Thoughts, ideas, arguments?.....

From: Frank Kirschner
Topic: 19805 Message: 19813

The suggestion to bend the ends (making a Z-shape viewed from above) is a good one. Most of the radiation comes from the middle half of the antenna, anyway. However, at only 35 feet, it won't be a great DX antenna.

Another alternative is to hide a vertical wire in one of the taller trees. If it's less than a quarter wavelength, you'd need a coil at the base. You'd need some radials, too. This would give you better DX than a low dipole. Twelve gauge insulated wire will carry the legal limit of power. Make sure the coil and connections at the base of the tree are covered or otherwise inaccessible.

I concur with Chris, WB5ITT. The results realized with the superflex are so insignificant that the instalation and connector problems become unreasonable.

Except only superflex is 100.0% shielded and 100% waterproof and has such low loss at high frequencies.

I had a similar problem at my former location in Ottawa re: OCF dipole and just mounted a short (10 ft) pole at the rear fence and bent the longer leg at 90 degrees near the end and down to the fence 20 feet away (bent leg was 10 ft) using PVC 45 angle elbow tethered from the pole. Seemed to work just as well as if it was straight.

No, folded dipole (two half wavelength elements "in parallel") by definition will occupy in theory same space / length! (+- some tweaking).

But you can let the ends go vertical as suggested.

The change in radiation pattern may not be worth to bother with,
especially on 80 and at 35 feet height.

Of course you can model it and see "how low (horizontal to vertical ratio) can you go" before it really became unusable as a simple dipole.

PS
Who told you you cannot have anything higher than 35 feet? Especially if you live near 100 plus feet tall sequoias? I think emergency services are pulling your leg , just to be ornery and feel important.

I do not want to get into lengthy "what if" discussion but Part 97 specifically talks about antenna height limits NEAR the airport.

And no, I am not suggesting that "also every emergency landing site" should be added to the Part 97 rules.

Those fly boys are well trained and can land anywhere they feel it is safe to do so, no more bureaucratic rules need to be added.

A few years back I was involved with our local SAR (search and rescue). The Highway Patrols chopper was designated H40 and they do not fly close to the ground and make circle an open field to make sure there are no obstructions in the way before they land. I would keep the pole lower than the tree. If you live in town I'd see the city fathers first for permission or just raise it higher at night. Hi Hi

A folded dipole is no shorter than a normal dipole! If your plain dipole is 120', your folded dipole would be 120', end-to-end, and it needs 240' of wire (plus the feedline).

What the folded dipole does, is make the feedpoint impedance higher (which can sometimes be beneficial with a low horizontal dipole to get the impedance back up into the ~50 ohm range). You also might get a tad wider bandwidth, but that's a secondary benefit.

not too many pines in town , mostly oaks and pecans and the ones that are here are between 40 and 60ft. am 25 miles from the airport , the EMS building and copter are 3 blocks north and 1 block south of me . I can hear when they start it . I have a 50 ft pole , will put it up and see if anyone notices .

19823. Something for every ham

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-18 00:36:02 UTC
From: kd8dvy@ymail.com
Topic: 19823 Message: 19823

Ok several days ago I got bored and snatched down my complete antenna system.

Some of you may think that this is crazy but it's not I did it for antenna maintenance.

1) removed support lines and shot news.
2) checked solder joints and shrink tubed protected the splices
3) reinforced the feed-line and center support
4) added an Inverted V doublet
5) new coax for the short run to the shack.

The reason I posted this is cause we talk about putting up antennas and how they act and how they receive. Well this is just a reminder that you should do antenna maintenance at lease one ever 5 years or so. If you can do it more often, like I do then that's great.

Just remember that we are only as good as our antennas and if you fore-go the maintenance and you are not as good as you once were then it may just be your antenna not you or the rig.

19824. long wire questions

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-18 19:42:09 UTC
From: Grady Hawkins
Topic: 19824 Message: 19824

I have 2 pieces of 14 awg thhn about 80 foot each. I am wanting to string out a long wire on a manual tuner or make a dipole. Since my neighborhood is not ham friendly and I have to be stealth, I think I am going to try long wire first. My biggest question is if you run window line or coax to the long wire from the shack, do you do anything with the other lead? Take it to ground or some radials? I am new to this but the experimenting is great. I just got my ticket a few months ago and I am currently running a 5BTV vertical. I raise it up when the sun goes down. Thanks, 73.

No, the high impedance twin lead goes to one end and the other wire in the twin lead is taped up
or heat shrunk to keep water out. This is a "Zep antenna look it up. It would really help if you
were to cut it to a 1/2 wl on the frequency that you most want to work.

Hi Grady

If you operate on one band only and use coax/twin feed half wavelength long you have a Zepp antenna. If you want to be multiband that is when things get a bit complicated, Then the inner of coax would go to long wire and sheild to earth stake/stakes/radials remember that if there is only one conductor it will radiate RF so if you have one conductor straight to long wire and shack ground there is a good chance you will have RF in the shack etc.

If you can try and run twin lead from tuner (better at higher impedances than coax) and once out of shack then just take one side down to earth stakes etc. I assume you are using a tuner if so there may be a internal balun but if not they are a doddle to make. You can either use torroids or ferrite rods, old AM radio internal antenna ferrite's work well and are cheap.

I seem to remember there is a website with the distances NOT to cut length to but cannot remember it at the moment I will look tomorrow if nobody else posts it. I think it was a Canadian Amateurs site.

19828. Recommended All-band antennas for backpacking?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-19 00:49:55 UTC
From: Jeri
Topic: 19828 Message: 19828

I have an FT-817 5-watt rig and an LDG Z817 tuner. I live in Los Angeles, only an hour away from the Angeles National Forest (with lots of trees and deep ravines I can use to string an antenna to/over).

I'm looking for a good antenna design that will cover every one of the US Ham Bands, 160 through 10 (with the use of the tuner, of course), and will be portable enough for backpacking. I am especially looking for a single antenna, one which will cover all the bands, without my needing to take it down and change it/tune it for each band.

My first idea would be a random-length wire Dipole/Doublet, about 260 feet or so of 20awg to 26awg wire, supported from the trees or across the ravines with some thin cord or Dacron fishing line. I would feed it with parallel line, probably 300 ohm twinlead, just long enough to go from the middle of the antenna to the tuner, with a homemade balun as needed at the tuner end.

I know there is someone out there who has already designed and is using this type of all-band antenna. So, what has your experience been? What length did you use to get all bands, and what balun ratio?

That would be just about the simplest antenna, and probably the lightest antenna, I could think of. And it would have good gain (but poor antenna patterns) on all bands, if I can get it down to about 6:1 SWR on all the bands that is, so the tuner could take it from there.

If another type of antenna would be better and handle all the bands, I would be interested in that one too.

I haven't really seen any direct discussion on an all-band antenna on the Internet (I searched). Usually, the discussion is about an antenna that has a low SWR on "all" bands, but skips certain bands because the SWR isn't low enough there (like a G5RV), or talks in general terms about the theory of an antenna, but gives no practical experience.

Any ideas? Has anyone out there put together an antenna that covers all bands, and is light enough to carry around all day?

Jerry

14 thnn in not really stealthy . I used to be in a neighborhood like that and made my G5RV antenna from 1/16 " galvanize lift cable after it has been up for a couple of months it turned a dull grey colour and was almost invisable I did not use any end insulators and had no problems . the window line was the most visible item but I had it in the back yard and no one ever noticed it . if you have trees in the right places you can hide it in the trees . It was actually touching a limb but I did not have any problems and was running 100 watts however it should be in the clear if at all possible .
I think I may have a photo of it and if I do I will put it in the photo section . it is also inexpensive . I got all the parts to make it for less than 15 dollars .

Topic: 19824 Message: 19830

Andrew has some good points, don’t let the antenna Ex-Spurts** jump in and talk about steel having more resistance. The 1/16 cable he speaks of will do just fine, you might be ½ of 6% of a dB loss in 2000 miles but it will work. I have used galvanized cable and SS safety wire , it all works. You could put up the wire and no one would notice, a 20m beam on a tower is different but a wire is not a eye sore and would be hard to see.

The only Antenna I can think of that might do the job is a W3EDP, I have tried this in practice and it definite does work. whether there is something better or more effective I do not know but would be interested to find out.

Here's another site that lists good lengths to use with a 9:1 UNUN:

http://www.balundesigns.com/Wire%20Length%20for%209132s.pdf

Click on the link in the middle of the page for the table of lengths. There are several lengths that provide good SWRs from 160 to 6 meters.

They're selling an UNUN, but you could build your own, especially if you're using lower power. A good ground/counterpoise would improve your signal.

Grady,
One possible configuration is an end fed. See attached link.
http://www.balundesigns.com/servlet/the-106/9-cln-1-9-dsh-1-unun/Detail

I use a similar arrangement. Is it the best? No, but it is stealthy & EZ. I use it on 80M & 160M for non-DX work. If you have any questions you can email me or we can even talk - 73

Grady,
I think you got some good advise here.

Just FYI
Long wire and Zepp antennas are not the same.
Zepp is still a dipole and long wire is generally longer than dipole and sometime of random length not related to frequency in use.
Zepp as dipole is preferable to work on design frequency.
Both are high impedance antennas and need to be matched to your rig
using suitable feed line and / or balun.
Feeding Zepp directly using coax will give you good radiating dummy load at the best and your not ham friendly hood may became hostile.

I never had any kind of vertical except for a short CB vertical on the house in houston , the neighborhood antenna nazis never said anything about it as it was used for the area COP's group . I moved from there in 2003 to La Grange in an area that has no restrictions within reason , I might get some complaints if I put up a 75 metre yagi but my dipoles work well enough . I had my HF antenna mounted to my truck and they could not do anything about that .

Dave,

From what I found, it looks like am 80M-ish end-fed antenna. I would have to experiment with it to make it cover 160M too. And the descriptions say you need several different counterpoises, different for each band.

Overall, it looks like it is a good restricted-length antenna. But out in the woods, there are no such length restrictions, as long as I can get the ends up into a set of trees far enough apart. And in the Angeles Forest, the problem may be trying to find an area where I don't have to thread the antenna through other trees.

19844. Folded Doublet Using Zip Cord Instead of Twin Lead?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-20 12:49:01 UTC
From: kd0ca
Topic: 19844 Message: 19844

I'm thinking about making an RXO Unitenna, published by G3RXO. It is a Folded doublet, fed off center, and is deployed vertically. You can learn more about it at http://www.standardtrees.co.uk/RXO-Unitenna.pdf.

My question is if I made a folded doublet like this out of zip cord instead of slotted line or TV twinlead, would it still be OK in your opinion? I guess I can find ladder line or such easily, but wonder if the low cost electric Zip Cord wtih 16 or 18 Gauge insulated wire would suffice? Thanks for any light you can shed on this.

From: Frank Kirschner
Topic: 19844 Message: 19845

The problem is that zip cord has a very different characteristic impedance from the 450-ohm ladder line or 300-ohm twinlead suggested. Depending on the diameter of the wires and the distance between them, the impedance is probably around 70 to 200 ohms (just a guess). The length, impedance, and performance would be different from that shown in G3RXO's report.

If you try it, please let us know about your experiences.

The link is stale or incorrect so we can't see it. Zip cord generally has a surge impedance of
about 60-70 ohms. (works very well with dipoles)

Sorry about the stale link. I think this one should work, at least it worked for me:
http://vk6nu.files.wordpress.com/2007/06/rxo-unitenna.pdf

I realize that zip cord has lots written about it both for and against, but its impedance should be of no consequence, as it will NOT be used as a feeder. I intend to feed with 300 ohm window line or twinlead. As soon as I try it, I will report back how it works. I should make 2 of them, one with "real" twin lead and one with zip cord just to see.

Even if it's only used as the antenna itself, its characteristic impedance makes a difference. Exactly what that difference would be is hard to predict. The net result might be that you need to alter the length to get it to work.

Generally, a folded dipole has about 300 ohms impedance. This antenna is not a half wave, and is not center-fed, so the impedance varies considerably over the 3:1 frequency range. The dimensions he gives are calculated to make the impedance something close to 300 ohms in the ham bands of choice. Changing the characteristic impedance of the antenna itself may vary the input impedance in ways that are hard to predict.

The second link worked just fine. I agree, the twin leads impedance is irreverent here.
I would recommend 300 Ohm twin lead over the zip cord, because the twin lead is insulated with
polyethylene a good electrical material and it weathers better, it may be lighter, the zip cord we
don't know. I wonder what this antenna's impedance is on whatever bands it is supposed to be usable on.

19855. Velocity factor effect on wire antenna length

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-20 16:07:23 UTC
From: vaclav_sal
Topic: 19824 Message: 19855

I am little confused about this subject.

I am building experimental / temporary array using 24 gauge telephone cross connect / jumper wire.
I am not sure about what is the actual material used in insulation.
It seems to be "advertized " as PVC.
I found that PVC has the lowest velocity factor of any material - (in telephone usage it is in audio range of frequencies) ranging anywhere from .6 to .4.

Does that mean that the antenna element could be almost half as long as the modeling software , which did not include velocity factor in calculations , determined?

One source sad that velocity factor may be only few percent.
50 % is definetly not "few".

I was thinking about stripping the insulation, but it is not that easy and pulling it off seems to stretch the wire core. Besides , the wire gets too hard to handle ☐ it twist like a snake without the added insulation.

I think the best way to fix this will be to made test antenna , one with and one withtout the insulation and actually measure the resonnace. And than I will have a better idea what is really necessary to bring the array into frequency of interest.

Any constructive comments will be greatly appreciated.

From: Andy
Topic: 19824 Message: 19856

The effect of the insulating material depends also on its thickness.
If only a very thin coat, most of the electric field is outside the
insulator, in air, where the dielectric constant is 1.

If you buried your elements in solid PVC and there was no air, then
yes it probably would need to be half as long as in air.

Making the elements shorter is a combination of velocity factor, as
well as coupling from the elements to other objects. Even bare metal
elements usually need to be made a little shorter than theory says.

Any kind will work, but you need to dig out the foam everywhere you cut it and put a daub of
silicone sealer in there to prevent it from filling with water, or melt the end over and bend it so
the opening is facing down. Walmart, Home Depot and others use to sell the flat cheap stuff.

I built the rxo vertical ocf doublet and yes it is quiet, but it is quiet because it attenuates the signals. I compared it side-by-side with another vertical and the vertical OCF doublet attenuated the signals by at least 3 S-units from the other vertical (sometimes more). A friend of mine built one as well with the same results. It does load up great on 40 thru 10 meters, but it just doesn't have the "ears" it should. Note that even though the signals were attenuated - if I could hear them I could work them, but there were several weak signals I could hear with my other vertical, but not the rxo. Can anyone explain why for me? Bill, AD0CW

Hi Jerry,

you mention that you want an all-band antenna including 160m, that you will be runnning QRP and that you wanted something portable. Here in the UK this is a very popular QRP antenna configuration. The point of maximum current is high up in the antenna and therefore it radiates effectively.

Personally I would use this antenna with a 4:1 balun with 85 feet of wire and the 17 feet counterpoise connected all the time on all bands but you could also try to connect dirrect to your ATU as well. An antenna on 160 metres will be very long and heavy but I found this antenna radiated well on top band all around the UK with an FT817 and I wAs using a ZM4 balanced antenna tuner. For simplicity and effectiveness I found it excellent and only found a doublet that equalled it but which was too big and too heavy for 160m and less easy to erect.

19864. My First HF Antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-21 11:38:45 UTC
From: james_nf8i
Topic: 19864 Message: 19864

Hi all,

I'm planning to get my first HF rig, but I don't want to buy any equipment until I solve my antenna dilemma. Like many in this group, HOA restrictions constrain me to only using indoor antennas.

I'm currently considering the AlphaDelta DX-EE or the Cobra UltraLite Kid for installation in my attic. My attic is only 30 feet long, though, and each of these antennas is about 40 feet. My attic is not high enough to run these as an inverted-V. My thought is that I could run the ends straight down from the roofline, which they should have the space to do without any additional folding.

My preference would be to feed the antenna with coax so I can run it through the walls from the attic to my shack, which is about a 50 foot run.

Some questions:

Is this a reasonable plan?
Should I put an antenna tuner at the feed point or in my shack?
What sort of directionality should I expect? (Putting a rotor on the house has been nixed by my XYL.)
Is there a better solution? (I have also considered magnetic loop antennas.)

I want to be able to work 40m, 20m, and 10m, with bands in between as a bonus, if possible.

Thanks, and 73 de NF8I,

~James

My educated guess is you can't beat a self resonant antenna.

From: Frank Kirschner
Topic: 19864 Message: 19866

James,

Yes, it's a reasonable plan. I had a fan dipole in my attic which worked out OK. It had elements for 40/15, 30, and 20. (No coils or traps like the antennas you are considering.) The ends of the 40 meter elements were folded sideways, making a "Z" as seen from above. I didn't have the height to let them go straight down. I worked Australia and New Zealand, as well as lots of European DX and got my WAS using that antenna, so an attic antenna can work.

The SWR is fairly high on 40 meters on the antennas you mentioned, so you'll encounter less coax loss with the tuner close to the antenna. You'll probably get a little less RF in the shack, too. Be prepared to put a counterpoise on the rig for each band you want to work. Also note that your signal will get into the AC, cable TV wiring, and anything else that runs in the attic, unless you're running QRP.

A dipole is supposed to be slightly directional broadside to the antenna, but it is affected by the proximity of other conductors, so it's difficult to predict. See if you can get the XYL to reconsider putting a rotor on the house. Tell her how much she'll enjoy the constantly changing view from each window.

I also tried an MFJ apartment antenna mounted outside a window. It worked, but the attic dipole was as good or better, and didn't require setting up and taking down each time.

I also considered the magnetic loop antenna. I've never seen a comparison between an indoor dipole and an indoor magnetic loop, but I'm told that a full-sized dipole outside beats the magnetic loop outside every time. If you put up both, I'd be very interested in the results.

Other things to consider: hide a radial system in the grass and sneak a screwdriver antenna out after dark. I did this, and worked 24 states in about an hour on 160 CW (during a contest). If basketball backstops or patio umbrellas are allowed, you can fabricate one from plastic and hide the screwdriver antenna in one of those. You could also load up the rain gutters, but that takes considerable work to make happen. (You have to bond all the sections together, install a radial or counterpoise system, and make sure to isolate the active section from any sections that are within reach of people on the ground.)

Good luck, and good DX!

That is only one interpretation. Thinking the restrictions prevent you from using an outside
antenna is a restriction in your mind only. You are not allowed to have anything on your property
that looks like an antenna. Thousands of HAMs have outside antennas that do not look like antennas
now. They use as many tricks as there are HAMs doing it.

flagpole
light poles
Bird feeder
arbor
under the eves
30 gauge dipoles
pole surrounded by a round flower garden, pole supporting hanging baskets (on nylon cordage)
with plants in them
HAM-stick on the back bumper of a car parked in the driveway with the coax coming under the car and
garage door into the shack

Antennas in attics if there is any kind of air-conditioning ducts or wiring are very troublesome.

Hams are too small a minority to get these rules overturned, but as you point out, there are ways around them. My HOA wouldn't allow flagpoles, but would allow basketball backstops and bird feeders.

If you do the mobile antenna-to-fixed-rig connection, don't forget to disconnect the coax before you drive away the next morning. That's the hard way to go mobile.

And you're right about the metal in that attic wreaking havoc with the attic dipole operation. I probably put more than half my power into the air conditioning ducts, cable TV wiring, and AC power cables. Nonetheless, on the bands on which it loaded up, the attic dipole generally outperformed the screwdriver antenna in the back yard. I had 25 radials laid out in the yard, and hid the coax and DC control cable in the grass. On receive and transmit, the dipole usually did better.

I would say don’t do it. Put up a 20M dipole, if you have to bend the end a little it will still work. After some exciting European contacts add a 15 and 10m element. Homemade is always better, cheaper and feels better.

Hi James,

I helped put up a 40 meter loop in a dudes back yard in Stockton, CA. He uses a 1.5 KW Tube Amp and he loves it. The wire goes thru his trees but after we put it up nobody could see the antenna. I think the antenna is about 15’ or so in the backyard and higher at the house.

Thanks for the actual usage report, Bill, and thanks, also to Ron KA4INM, for valuable input.

I wrote an email to Roger, G3RXO to ask him about the idea. He cautioned agains lamp cord (zip cord) as leakage across closely spaced conductors at high voltage points can be significant in wet weather. Using the zip cord would be asking for trouble in my estimation, then. Using wider spaced conductors like 450 Ohm line would be a wiser choice.

Since the antenna is purposely Non-Resonant on the ham bands until one tunes it via an ATU and zepp feeders, inefficiency is the probable cause of the weak received signals. With a tuned feeder, we can match almost any metal object, but that in itself does not mean it will be a "GOOD" antenna, Hi.

By the way, just because an antenna is non-resonant on any amateur band does not necessarily mean that the antenna system is always "bad" either. I use an Inverted L wire 81 feet long, vertical leg is 20 feet, and I'm amazed at some of the great reports I consistently get both with QRP and 100 W rigs! I also have a 19 foot tall vertical with just 1 wire radial which I feed with 300 Ohm ladder line. I've had great success with it, although I need to take it apart sand clean the joints so it will work better. On some signals, the Vert is WAY better on 20 Meters, but on others the INV L is better. Often digital signals are not visible on the waterfall with the Vert, but are really cleanly visible on the L.

Maybe the Vertical Folded OCFD is not a great idea for me right now. Great to hear others' experience whether positive of negative.

These "deed restrictions" can not be overturned, they are "covenants"
to the deed, a freely signed* contract between the buyer and the H.O. association,
they are a legal civil contract.

You can get a special PL-259 that pushes on and pulls off, I have one, try a CB shop after looking at your next HAM-fest. Be sure the antenna's connector is facing the building.

* but none the less required before you can purchase the property.

I rather ike the idea of, say, a loop around the house under the eaves or gutters. I'm a bit worried about the interaction with the aluminum siding though.

I'm not terribly handy, so I'd need to overcome both my poor grasp on antenna theory and my general clumsiness when working with my hands.

I just got a copy of RSGB's Stealth Antennas book, so I may have to revisit the question after reading that.

(Of course, I could better fit in with my neighbors by putting a dummy satellite dish on the roof and draping coax all over the house.)

Sig I have a better scenario:

No push on used ... xyl borrows car .... trx jumps from desk and is flying out of the window ... Rig is destroyed.... xyl has to buy you a new one... you say the only equivalent that is made now is a K2....

Sounds good to me.... I'll be back later after I hook up to the car.

the 6-Lander should check about flagpoles CCRs can be voided and one
way is if the legislature does it and back in 01, after 9/11, 6-Land
legislature passed a law, signed byh Governor Gray, which prohibited
enforcing CCRs that prohinbiting flying a flag

Actually, it depends.

In my part of the country (upstate NY), deed covenants are common but HOAs are not.

I once bought a house that has been built just after WWII. The deed forbade selling the house to non-caucasians and required servants to be let in only by a side entrance. Servants for the owners of a 1200 square foot 2 bedroom Cape Cod. Indeed. At any rate, those covenants had been unenforceable by law for at least 25 years prior to my purchase. But they were there in the deed nevertheless.

Another house had the usual restrictions: no outdoor clotheslines, no parking in the driveway overnight, etc. My attorney pointed out at the closing that enforcement was left to the original developer who no longer owned any land in the development and thus, under NYS law, had no standing to enforce the covenants. Effectively, no covenants.

In my area, they got around this by allowing flag poles attached to the house not exceeding three feet in length. I could have put a little antenna in that, but there were better solutions.

Good idea, though.

We will be watching to see what the supreme court says about this one.

Even Better: Sudden and Accidental qualifies it under most
homeowners insurance as accident to personal property.

Wife says: Talk to our insurance company, it wasn't MY fault.....<heh,heh>
Been there, done that..... (and yes, I now have slip-on coax connectors!)
This is about as 'sudden and accidental' as it gets!

next car you get make sure it is one of the keyless ones with a push to start/stop button and keep the little transmitter that tells it you are the owner in your pocket . xyl borrows car and finds it will not start .

.... xyl has to buy you a new one...

Joe: And HOW long have you been married? After TWO ex-xyl's, I know it's
the OM
that buys the new rig...IF the XYL let's you have the checkbook..or one of
YOUR
Credit Cards.
My 2 cents worth!

Steal an Idea from "Rat Shack" (IIRC) wrap a VHF/UHF antenna around the
outside of the dish like they did to receive "Local" TV channels back when
there were "Analog" signals!

Sounds like my first XYL. If she was driving the car and any warning lights or BUZZERS came on she would drive it home < Or TRY> to ask me what was wrong with it.
After replacing (2) TWO Turbo Corvair Corissa engines at $2,000.00+ (1968 prices) I fixed a timer and told her if she saw a light or heard a buzzer pull to side of road and turn engine off within 30 seconds.
She ignored it, she parked the car in the middle of the Santa Monica Freeway, LA at 5:45 PM! Repair cost $20.00 to me she paid the $75.00 ticket and the $95.00 tow bill.
She NEVER did that again.
Oh for the days when you had TUBE time delays.

James,

It is just easier to send this directly to you rather than post to ham-antennas because I can't post images there. I CC'd the list, but I don't think they will get the image.

This arrangement requires access to the attic.

The attached image is a diagram of the antenna at the condo I lived in for 7 years. Condo satellite view courtesy of Goodle Earth. The antenna is fed in the center on the ridgeline. The sketch is of a dipole, but it was too much trouble to draw two halves of the dipole using the ruler in Google Earth, so you'll just have to mentally insert the center insulator and feed point in the center of the ridgeline.

I used a length of about 66 feet for 40 meters. The sketch shown is reported by Google Earth as 102 feet. You just toy with the ends by folding them back, and let the autotuner take care of getting a reasonable match. I didn't have an autotuner back then, but my 40-meter dipole, folded into something like the letter C, worked OK. For ease of adjustment, you might try feeding at the eave, and doing the foldback of the elements along the ridgeline. The roof area was non-metallic, but the siding was aluminum.

The house construction was a quad, and my piece of the property was just the quarter where you see the antenna in yellow.

Robert, NX3S

19890. A-D DX-CC for sale

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-24 06:43:55 UTC
From: Chris Boone
Topic: 19890 Message: 19890

Selling for a friend of mine who is going into assisted living.

An Alpha Delta DX-CC antenna..with a MFJ259 antenna analyzer on it, it showed the following:

50ohm match at 3770 (same as A-D's ad)

50ohm match at 7100 (again, same as A-D)

50ohm match at 13.880 (ok, this is a little low; just trim the 20m element)

NO match across 15 (and A-D says use a tuner..the SWR was below 3:1 in most spots so a tuner would work ok)

Couple of low SWR spots on 10m..ok on 10m

Sells for $180 new..asking $120 +S/H OBO

Can do Paypal.Includes 75-100ft of LMR 400.will have to cut one connector off to pull it back through wall but can crimp a new one one for buyer

Chris

WB5ITT

Wb5itt at wb5itt dot net

(CAN Deliver to Belton Hamfest or along route to/from it.coming from Beaumont to Houston northside to 290 to Brenham and then 36 north to Cameron to 190 and then on to 93 to Belton)

Good antenna, use mine to back up my Cobra but it is too "ham banded" for my MARS usage. point is, MFJ shows a "259B" for about $290.. that plus the DX-CC and all that wire makes this a real steal at $120.

Whoever buys this will have really "fallen into it" so congrats to whoever...

The way I read it is Chris is simply using HIS 259B to show the swr points,
but it does NOT come with the 259B.

19896. Hustler G7-144 or Diamond X-500HNA

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-25 11:10:18 UTC
From: Zoli
Topic: 19896 Message: 19896

Hi all!

1.I like to know that G7-144 or Diamond X-500HNA has better gain for 144mhz band on the same mast if you hear a repeater?

2.I like to know that G6-440 or Diamond X-500HNA has better gain for 430mhz band on the same mast if you hear a repeater?

3.X-500HNA(5.4m) is longer than Hustler G6-440 but I am dissapointed for 430Mhz band.I like also X-700H dual band antenna(7.2m) but I am afraid of 70cm gain.One times tested X-700H and X-50(1.7m) and X-700(7.2m) was same on 70cm.On 144Mhz was difference about S3 signal. Experience?

4.I heard that same years later radial of G7-144 fall out.
I dont understand that radial made from aluminium,why not from stainless steel?This antenna has this radial problem now?
Do you suggest to buy this G7-144?

Thanks
Zoli

Hi Zoli

I have the Diamond X-50 and Watson W-2000 which replaced my X-50 both excellent antennas and only replaced the Diamond as the Watson was the "right" price and had 6m capability. I have found my FT-450 running 100W via an old MFJ-948 gets out well on 6m. My OCFD will tune on 6 but in all honesty the Watson is at least 3 S points better.

From Eham reviews the X-500HNA seems to be not the best but I would recommend the X-50 or Watson equivalent if you want to save a few pennies and in my case both antennas have stainless radials.

Hi Zoli
I had them both did a A/b for the most part they are almost even the g7
was just slightly better on receive
however when the wind starts blowing 15 to 20 mph the flutter is brutal
on the Diamond 500.

19899. G7 vs Diamond/Comet

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-25 17:04:35 UTC
From: Chris Boone
Topic: 19899 Message: 19899

Hustler G7 wins HANDS DOWN against ALL competition.....even a DB224 watt for watt in range....NOW if its on a tall tower (500ft or so), you DON'T want it to be the TOP antenna...it does NOT like lightning the way a DB224 can handle it...(been there, lost a couple and its not a pretty sight)..and the DB224 can be pattern shaped where as the G7 likes to be omni more than anything else.

BUT performance, GIVE ME A G7 anyday....even the G6 is fantastic....YES 6 and 7 REAL DB gain over a DIPOLE (dbD) not over an imaginary antenna (dbi) which raised the number by 2.15!!! (ANYTIME you see dbi OR even more likely db with NO D or d at the end, its dbi and that number is 2.15db HIGHER than dbD real life gain)

Yes, the radials are aluminum....go to a hardware store and buy some stainless roads if you wish or spray the radials with a good enamel paint and clearcoat like used on autos.....but the mast too is aluminum (I use clear coat on that as well)....one local 2m rptr has a G7 on it since 1984 (I put it on the tower!!!); yep the radials are gone....surprised the antenna is there...but hey 150 bucks for an antenna that lasted 20yr in the SE TX corrosive atmosphere is a pretty good ROI !!! DB224s may go longer but they cost 5x as much....ON a short tower or building top, I PREFER the G7 for omni coverage...not easy to use in directional mode unless you space it 1/4wl from a suitable mast behind it as a reflector...On a tall tower, I don't like to climb..but side mounted, they seem to hold ok..its just when IT is the lightning rod, they explode....(and yet keep working as a single 5/8wave antenna!!! Had that happen at a rptr site 3 years in a row on Labor Day weekend back in the 80s....N5DNG(sk) in Daisetta TX between Beaumont and Houston...200ft high G7s on 2 and 220....the 2m kept getting blown away by lightning storms...The 220?? NEVER took a hit.....we eventually put a taller lightning "mast" up and the G7-144 never blew up again....

Chris
WB5ITT
(LOVE the GX-xxx series...except the G6-2/70 is not my fav but it is still REAL 6dbd on both bands..unlike Diamond or Comet (and Ive tried them all)....I DO like the Comet CX333 tribander...but the fiberglass and radials tend to fall apart after only 2-3 years...yet a G7 on the same roof top?? Still going strong 15 years after it was installed new....THATS performance)

19900. diamond dual band antennas problem on 70cm X-50,X-200,X-300,X-500,X-510,X-700

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-25 17:14:36 UTC
From: Zoli
Topic: 19900 Message: 19900

Hi all!

1.Who compared one of Diamond dual band(2m/70cm) antennas on 70cm band with other vertical antenna(Diamond monoband 70cm...) on the same mast on the same time?What is difference?I think on 70cm band diamond dual band antenna not working.

2.I used Diamond X-50 and X-500 and X-700 and realised that no difference on 70cm band.Longer Diamond dual band antenna is not better than shorter Diamond antenna on 70cm band.Why?

Thanks
Zoli

19901. 3 element wire beam

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-25 18:10:58 UTC
From: wb4mnk@bellsouth.net
Topic: 19901 Message: 19901

Wonder if some one could model this antenna using EZNEC program.

Director : 32'1"
Driven ele: 33'8"
Reflector: 35'8"

Spacing of 8'6" for both the reflector and director.
Wire elements are config. as an inverted vee with the peak at 19'and apex angle 90 degrees.
Feed line is rg58 50 ohm belden cable 50 or 75 feet long.
Elements #20 gage teflon coated copper wire.
Ground will vary because the antenna will be used qrp portable.
Output will be 4 watts to this antenna.

I am interested in the:
Gain, Angle of radiation, and if possible a picture of the radiating pattern.

I have tried to use the program to get this information but just don't have the knowledge and experience to use the EZNEC program.

Any help will be appreciated.

73,
Art

19903. Comments welcomed

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-25 19:37:58 UTC
From: neilkj6fba
Topic: 19903 Message: 19903

I am a newly passed General Class amateur and wrestling with antenna issues. My home owners association is pretty fussy about "visible antennas". For my UHF - VHF antenna I have been using a Diamond discone which is hidden from street view behind a medium sized pine tree. For my SWL over the past few years I have a random wire, about 140 feet long running along the top of a wooden fence about 6 feet high. It is fed by about 40 feet of quality RG6 "quad-shield" coax and a "balun" (un-un) from Par electronics. I know I could replace the coax and balun but would like to avoid that cost if feasible!

Now, I know the coax is 72 ohm impedance, not the recommended 50 ohms. I am still shopping for a transceiver of about 100 watts PEP and probably an antenna tuner which could cope with the 72 ohm coax and a random wire! I would like to get a transceiver AND an antenna tuner for less than $1500 total cost. I know I will likely need to buy a power supply as well.

Any suggestions or comments are more than welcome.

19905. slim jim antenna freq

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-25 22:32:22 UTC
From: tivoligardens@yahoo.com
Topic: 19905 Message: 19905

I built my first slim jim using twin lead today.
When I put it on an antenna analyzer it come up with a freq of 167.2.

What do I need to get this town for use on 2m ?

Thanks
Hal W4Hal

19906. Phasing Yagis in Vertical Polarization

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-25 23:25:19 UTC
From: Terry Maurice
Topic: 19906 Message: 19906

Hello all,

This is my first post to the group and this topic may have been covered before but I have been unable to find it.

I am attempting to setup two 15 element Yagi antennas in vertical polarization for the 70cm band and I am wondering what the spacing should be between the antennas. The ARRL Antenna Handbook states that 5/8 lambda should be used for best gain and pattern, but other sources on the net indicate that a wider spacing up to 1.3 lambda should be used when a larger number of elements are present in the Yagi. I am using a Yaesu G-5400B rotator system with the elevation rotator at the top of the mast and the azimuth rotator down in the tower.

I would appreciate hearing of any experience you have with such a setup.

Thanks

Terry

Well John, a bunch of people will tell me how wrong I am but I had one made from a 1x4 piece of white pine for years. Grounding is thru my tower and other points not just at pass thru. Since I moved out here this one is made from polycarbonate, coax is thru with a little calk on some and extended PL-258's (bulkhead fittings) on others, rotor control cable just a little RTV also. The 450 ohm line has the ceramic pass thrus but a hole and RTV would be just as good. On the outside I support the coax runs with a strip of poly and then clamped with Adell clamps and supported by 1/16 cable and a spring. This keeps the wind load off the pass thru. I like to make whatever I can and it's cheaper. There is a picture in the photo section of this in the Kd0zz album in the groups photo section.

Or for more of my crazy ideas see,

Or adjust the feed point. Don't rely on what the drawing says for coax attachment.

Use the analyser to get the correct feed point position.

I assume you mean that the resonate frequency is at 167.2. If so then check you dimensions , it sounds like your upper legs are too short, but that would be a extreme amount, close to 9" overall.

Did you adjust you feed point for lowest SWR?

Try out mmana!
freeware and easy to use antenna simulating soft
I made LOTS of antennas with it ... and I think it is quite easy to use
(after a short learning curve)
I can model your antenna in minutes with this soft
Ok sure you would need a bit time for learning how to use it ... but after
that you will not use any other soft again (my thoughts)

The sources on the net are right
With very long beam antennas you need a wider spacing ...
For stacking antennas you should look for a clean pattern (low side-lobes)
Instead of the max gain it is better to have a cleaner pattern
You will not notice a difference of a few tenth of db in gain ... but lower sidelobes is good for better receiving (lower noise from the sides)
...
Best would be to simulate your antennas ... but i think if you take the recommended stacking distance all should be fine

See in the tables of different antenna manufacturers ... there is a recommended stacking distance for a given antenna

Take one antenna that is close to your design ...
A small difference is meaningless for the gain and pattern

You wanna spend 1500 bucks for trx and tuner ... but want to avid the costs
of a few feet of wire ?!?! ...
A used trx can be found for 300-500 bucks (depends on what you want)
Or you can spend 1500 bucks for a new trx with built-in tuner
(or a bit lower to have some money left for psu)

I would recommend to buy a used trx and a manual tuner first ...

That should be in the 500 dollar range or so

The saved money could be used to buy some new coax, a power supply (if you
bought a mobile rig), and a spool of aluminium fence wire (30bucks only)

Ask your ham-friends in your local club if someone has a spare rig to sell

Go to the next ham-fest and see if someone on the flew-market has a rig for
you ...

For a beginner I would not recommend to use an sdr rig a starting point ...
otherwise I would maybe take the flex 3000 ... 100w with built-in tuner

19918. AW: [ham-antennas] diamond dual band antennas problem on 70cm X-50,X-200,X-300,X-500,X-510,X-700

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-26 10:22:04 UTC
From: Siegfried Jackstien
Topic: 19900 Message: 19918

Sure there is a difference between x50 and x510 ...
The longer antenna has a few db higher gain .. but only a few db so not easy to measure that with a s-meter in the rig
I changed my x6000 (triband 2m, 70cm, 23cm) against a x510 ... that few db more give me exactly one repeater more :-)

I have a very far away repeater on 70 (db0hex abt 200km away)
With the shorter antenna I can work the repeater only on some days
With the longer x510 I can work over that repeater daily ...
The problem on the very long antennas is fading if it is windy ... but the gain is there!

I also compared the original with a clone from a different manufacturer

Buy the original!!! The clone antennas are not so good
The different parts on the antenna (the stacked elements) were connected with crimp connections ... but these connections were "loose" ... I had to additionally solder them to give a good contact!!!

In the elements there are some series caps in line
In the original that is done with small tube parts
(tubular condensator with air as isolation)
In the clone model small ceramic caps are used

And the stacking is made different
On the original the stacking elements (phase line) is done with a real line that goes from lower element up, ent bdown again, and again up
(three-folded element of length 1/6wl=1/2 wl)
On the clone there is a very long but thin coil ... guess what .. the coil has way higher losses ... and so the stacking gain is lower on the "clone" model ....
Been there done that :-)
So ... look to get an original diamond x510
Control the crimp-connections before putting up to roof or pole
(yes even in original I had to additionally solder the connections!)

From when I was playing with moonbounce a rule of thumb was to make
sure the antennas capture areas would never touch.

I agree find a good used TXRX or get something from Yeasu if it is possible to run some more wire to completely bring the antenna back around to the balun then you will have a loop which should work fine for you.

$1500?

Easy for all new no slouch system FT450D new version with ATU for somewhat resonant antennas $900 or Icom 7200 no tuner $1000 Astron RS35m with volt and ammeter $169. (Mine has had little downtime in nine years.) Plenty of room left for coax and wire or hopefully not..... commercial antenna. Best bet for budget and very decent performance on antenna would be a fan dipole as you would only invest in one piece of coax, 2-259 connectors and antenna wire. You could use a W2AU 1:1 balun from HRO $30, as it makes a very good center support and helps keep RF out of the shack for only a few dollars more than just a center connector. Had a fan dipole once and may wind up reverting to it again.....Biggest caution.....build it one band at a time....do not rush it. Start with the lowest band, tweak it and work your way up, at least that is the way I did it many years ago, with a 1:1 balun, and it worked fine, 40, 20, and 15, no TVI. I tweaked it as I added bands, and had it less than 1.5:1 everywhere I wanted to operate without an antenna tuner. With an internal tuner, a piece of cake. The G5RV I had here got into the TV with a rooftop antenna before I got satellite TV.

If you go with something like a G5RV, few if any internal tuners will handle it. You will be at your budget to get a good external tuner. The highest rated for 200 watts and down....Tokyo HI Power 200 AT at $300, IMO much better than LDG, just slightly more expensive. Have worked 17 countries in the last four weeks with just a 40 meter dipole with almost no effort.

If you are going to spend money on radios, start with a solid and simple antenna. You can use good antenna wire and low loss RG8X for budget construction and stealth. My feeds are 50 to 75 feet, so until I settle on exactly what will be long term for this location, the 1-1.3 db of loss for LOW LOSS RG8X vs RG8 is not a big deal, nor worth the extra sixty or seventy cents a foot when putting up five antennas.

Good luck and grads on the General....Now get to work on the EXTRA!

I agree. Having spent 20 years in the USAF (and years after that as a contractor), traveling all over the world, I always used cheap, easy-to-erect antennas. Now that I've finally settled down, there's no question that overall performance is better if you split the money, time, and effort more or less evenly between electronics and antennas. My old Omni V with a 102-ft doublet out-performs my FTdx-5000 with the Cushcraft R5 I used to carry around. I've picked the spot in my yard for the tower and Yagi.

If you want performance, pay more attention to your antenna. You can get a good used rig for $500 to $1000, depending on the bells and whistles you want (many of which you will wind up not using), and spend the rest on as good an antenna as your lot will allow.

If you have an HOA, consider moving. That's what I did.

My windows slide side to side. I just got a piece of wood the thickness of my window that was about 4” wide and bored 4 holes into it for the bulkhead extenders. Its not pretty but it gets the job done. A friend just bored holes in his wall to run the coax thru then put the PL-259 on the end when it was inside. We have another friend who used Lucite (Plexiglas) instead of wood.

No arguement on the rig. I think maybe, instead of an ebtry level radio, consider the next level up if yo ucan afford it. I started with an IC-735 but moved up to an IC-746Pro a year later. But you gotta start somewhere. I've heard that the TS-590 is a lot of bang for your buck. The ones I've heard on the air sound pretty good.

Concerning the G5RV, I've found the tuner in the 746 does a fine job on it with the exception of 17m. I had always heard grumbling about the G5RV, but after losing a tree which was one of three supports for a loop I had to put something up that only needed two supports and tried the G5RV. I am really surprised at how well it works, especially on 75m. On 40m I talked down to LA with < 10W. Completely anecdotal with no definitive testing, but pleasently surprising. Wonder antenna? No. But my point is that the tuner in my radio tunes it pretty well.

I've had a 135' doublet and found that to be a good performer, but it definitely needs a tuner with more range than an internal one.

guess I am lucky . all my coax passes into the basement through the hole in the floor where a heating pipe used to be and out through the bulkhead wall where the old water pipe came in . I know not everyone has a basement . they are rare in south texas .

Yep, you are probably right Bill as I was just reading about the dozen variants of the G5RV. Some are closer to resonant than others. Mine was off the chart everyone but worked OK with a manual tuner.

>
> No arguement on the rig. I think maybe, instead of an ebtry level radio, consider the next level up if yo ucan afford it. I started with an IC-735 but moved up to an IC-746Pro a year later. But you gotta start somewhere. I've heard that the TS-590 is a lot of bang for your buck. The ones I've heard on the air sound pretty good.
>
> Concerning the G5RV, I've found the tuner in the 746 does a fine job on it with the exception of 17m. I had always heard grumbling about the G5RV, but after losing a tree which was one of three supports for a loop I had to put something up that only needed two supports and tried the G5RV. I am really surprised at how well it works, especially on 75m. On 40m I talked down to LA with < 10W. Completely anecdotal with no definitive testing, but pleasently surprising. Wonder antenna? No. But my point is that the tuner in my radio tunes it pretty well.
>
> I've had a 135' doublet and found that to be a good performer, but it definitely needs a tuner with more range than an internal one.

I agree the G7 is good but you can make one with a stick of grey PVC and a little bit of wire. 5/8 lower section 3/8 hair pin to match and a 5/8 top section. There is a picture of one of mine in the photo section marked, 2m stacked. Lower is a standard J-Pole then a additional 5/8 wave on top. It is much easier to make then a coaxial collinear as a high gain 2m vert. The coaxial collinear can be made into a higher gain than the stacked J-Pole but you have to do a velocity factor adjustment for whatever you encapsulate it with so it can't be tested until complete and if a adjustment it needed you have many sections of coax to trim and solder back together.

Or, you can make a double 5/8 ths wave collinear as described below out of 1/2 inch copper pipe. Been running one since '94... fed with 450 ohm ladder line, a 300 ohm Q section and a half wave coaxial balun to get down to 50 ohms unbalanced at the shack.

Or you can just use the balun at the J section and run coax all the way. I just did it this way to have the least loss and to see if it'd work.

Either way... have fun.

Stan

19936. Before You Put The Coax Seal On That New Antenna.....

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-09-28 01:40:00 UTC
From: pchapman920
Topic: 19936 Message: 19936

Test it a lot. Rag chew, make a lot of contacts, cruise the band. I just made that mistake, and it does not come off very easily. It was a commercially made antenna. After setting to about ten watts on 20......hmmm...1.2:1 not so bad....lets find the flat spot to see if I need to let out or bring in the ends....move 50khz, still 10 watts...3-4 seconds key down.....then infinity SWR and signals vanish. A five foot open coax jumper pulls in signals better. This must be a hard short in the center feed capsule termination, or I did a bad solder job on the 259, and braid hair arced over..... Pulled the antenna down and separated the coax feed. Get out both my 40 year old analog and Fluke's Amprobe AM-60.....(So far a pretty decent auto or manual range meter with memory.) Coax is clean...even put gator clips on the 259's and swirled them in the air to try and re-create any possible shorts.....none.

Rather than worry about it today, I dug out a center insulator and some antenna wire and went back to work to get something in the air and on twenty. Should finish it tomorrow.

Getting new dipole up now kind of anti-climatic. The interesting part will be geting out the Dremel tool when I have time to open the capsule and examine the workmanship inside, and find out why it failed.

Topic: 19937 Message: 19937

Hi All

I am using a FT450 feeding a OCFD and crappie vertical half wave with coax switch and autotuner. I have just made a relay box similar to the one on the Royal Signals Amateur Radio Society website. ie. in the de energised state the antenna caox's are grounded both inner and shield. Straight through when energised (Sheild still grounded), each coax has 2 relays in parallel switching only the inner each rated at 12A .The relays are mounted on circuit board etched by me. So all working and connected it up to antennas and my LDG Z11 pro11 and it goes through tuning cycle when on a frequency that it was already tuned to. So just measured inductance and capacitance of unit as follows:-

Capacitance= 20pf relays energised and de-energised
Inductance= 120uH relays de-energised
each relay when energised adds a further 20uH

which I make the resonant frequency of the unit as 425Khz

So what I am asking is it OK to use? or should I redesign.

Thanks

Jon

It probably won't.

The chances are 99.999% that the email didn't come from your account, but from a spammer who says it was coming from you.

Yahoo does nothing to verify that email actually originates from the domain it claims to be from.

Marlin,

I had that happen to me awhile back but just changing the password doesn’t always help as in my case, I changed the password but spam was still being sent from my email account to everybody in my address book.

Here is what I did, I changed my password to something more secure and I made a database file and put “all” my contacts in that database file and then deleted them from my address book. Anytime I want to send somebody an email I go to the database file and click on their email address and it brings up email screen so I can send them an email. I also have to log in each time I want to check email unless I don’t close my email program.
Since doing that the spam has stopped.

Allan

The one highest in the air! Height is might on VHF/UHF so if possible spend extra time/money to get your VHF/UHF antenna as high as you can afford and safely do so, it will pay off for more coverage (you can have the best high gain antenna there is to buy or make but if you have it low to the ground for VHF/UHF your coverage will be less than less gain antenna high in the air to send that signal out over terrain/obstructions). While height is might, generally speaking, there is one major caveat.
That is feedline losses. It does not help to put an antenna so high
that all signals, both sent and received are pretty much absorbed in the
coax. I used to work at a site where we used VHF a lot. At one point,
management decided we needed a 300 foot tower. It was installed but the
antennas were almost useless until the feedline was replace with coax as
thick as my wrist. The other way to deal with this problem is to remote
the radio to the tower top. But be sure, heliax is your friend when it
comes to VHF or UHF and high towers.

Adrian: Now don't go showing off your lack of knowledge of vertical antennas. I think it would
be wise for you to "learn" a little bit about them, before making such a totally uninformed
statement. Read up on it a little...then come back to discuss it as a ham 'learning"
experience. Aaah..to be young again!

gain,longest)?

Whats the difference?

2 meter VERTICAL is 2 meter VERTICAL.

19957. Portable / Mobile NVIS Antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-01 16:33:08 UTC
From: Tom
Topic: 19957 Message: 19957

Anyone have success stories with portable NVIS antennas?
Presently I'm trying dual Hamsticks (dipole) mounted on a tripod between 5 and 8 feet above ground. Very poor performance compared to a standard 40/80 meter wire dipole at 6 feet above ground (as I would expect) I also have a couple of "BuddySticks" I'm going to try.
I'm really interested in building a magnetic loop antenna as in the camouflaged automobile "roof rack" design.
Some background:
http://www.stealth.ae/plugins/custompages/detinf.php?id=372&id_categorie\
s=136
<http://www.stealth.ae/plugins/custompages/detinf.php?id=372&id_categori\
es=136>

Also.....

Tie a retrieval line (light rope) to the insulator so that if the antenna wire breaks you will not have the insulator and support rope permanently stuck in the tree.

> Are we talking FM or SSB/CW. Just curious. I live in the mountains and hit a lot of repeaters not local. I’m mostly using 5 W’s of power. My Diamond X50 is up 20 ft. and works quite well.

Actually, I have had good results on 2M SSB and CW with antennas that were rooftop high. Typically 200 miles with 160W. With a KW, an ocean path and a 19 element antenna at 85 feet, 500 miles was readily possible on CW with just forward scatter and no ducting.

If your talking fm, height and coax are most important. Coax especially on 432. Get lmr400 if you can, about $1/ft

If your talking cw/ssb you need a horizontal sqalo, big wheel or beam.

A friend recently got some Davis rf buryflex compatible with lmr 400 for $1/ft from associated radio.
I have seen it for $3/ft also.

All it takes is a search on Google:

Keyword: Isopole

http://www.isopole.com/english/homeen/homeen.htm

http://www.isopole.com/english/products-en/products-en.htm

From the picture, is looks like this is the place. Those Isopoles look familiar. Originally offered by AEA. They might have sold the product line to Spectral.

I used a W2AU Balun with mine and was very happy with the results.
Pattern seemed more dead on, and it seemed quieter, Maybe the coax being
grounded at the feed point did that? But of course this was the big
brother also the TA-33 not junior.

How many loops? I guess this would serve as a balum. Can someone tell me a little more about the purpose of this? Also I'm putting a 2 meter Yagia on top of the tower above the TA33 JR, are there any certain distance that I need to put between them?

As has been pointed out before, it probably has nothing to do with his password. Spammers can send out email with any return email address they choose. They happened to use his this time. Changing his password won't stop that.

If they had logged into his account and used it to send out the spam, the messages would still be in his sent items folder. Most likely, they're not.

19986. G5RV or Buckmaster Diapole...why are some bare wire or coated? Is one better?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-03 17:21:56 UTC
From: kb1kln_73
Topic: 19986 Message: 19986

Hi,

I was wondering why I see advertized that the G5RV's sometimes come with bare braided wire or coated braided wire? Does one perform better than the other?

The Buckmasters seem to come coated only (or at least that's all I can find)?

Any thoughts on performance?

Thanks

Jon (KB1KLN), 73.

There's no difference in performance, but the bare wire will corrode faster, especially in a salt-air environment.

This is probably the dumb question of the month but.....

I have over 100 feet of stranded copper clad from an antenna I took down a while back. It has blackened from being in the elements for a number of years. I do not live in a salt air environment, so there is no burring or signs of corrosion. Have another antenna in mind I would like to build with it. Other than cleaning ends for solder joints, I can't think of any reason not to use it again.

Anyone know of a reason not to use it?

I bought a 2 meter Isopole from AEA in 1983. You have to supply the 10 foot pole. In 1999 I moved to a new QTH. Because I used Penatrox (Electrical ALU to COPPER Silcon Grease. It or the equivalent is found at Home Depot and many electrical supply houses) on the ALU skirts to the STEEL pole along with coax seal at the top of each of those funnel shaped skirts, the connection was like new. I redid it and put it up as a 2nd 2 meter antenna. It has about 5 db gain. Very rugged while in the air, easily bent or destroyed on the ground. Because the coax connection is internal, it is protected from the elements. For $40 more you can purchase a comet DB9 dual band, which is what I am using for my main 2 meter/440 antenna.

Do you mean under rated ? I have owned the Ham IV and Tail Twister's in the past without a failure other than burnt out light bulbs . I am overlooking a lightning strike. I changed to the Yaesu rotors several years ago because I was tired of watching the beams swing back and forth about 10 degrees with the brake locked . The Yaesu does not move once it is looked . It is a little more pricey . For several years it was easier to computer control but that is a toss up these days . Chuck Wq5B

19997. Re: [ham-antennas] Mosley TA33 and rotor sizing??

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-04 00:03:24 UTC
From: Walt
Topic: 19970 Message: 19997

I have used a Ham four with a 10 meter- 5 element inverted Y at 70 feet for several years, I had no noticeable swing to any degree. In fact several times the antenna itself would flex a great deal without the rotor turning. Can’t say other than what I observed many years ago when I had this setup.

Do you mean under rated ? I have owned the Ham IV and Tail Twister's in the past without a failure other than burnt out light bulbs . I am overlooking a lightning strike. I changed to the Yaesu rotors several years ago because I was tired of watching the beams swing back and forth about 10 degrees with the brake locked . The Yaesu does not move once it is looked . It is a little more pricey . For several years it was easier to computer control but that is a toss up these days . Chuck Wq5B

I've even used an alliance U-110 for the senior version.

Rotors are far over rated.

19998. Re: wire antenna knots

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-04 00:15:48 UTC
From: Bob
Topic: 19954 Message: 19998

Hi Brian
The bowline is a good knot for rough natural fibre ropes like hemp and sisal, however it can be prone to slipping in smooth synthetic ropes like polypropylene and nylon. A better knot for synthetic rope is the figure eight loop, which is used by mountain climbers when they have to trust their lives to their knots.

Well....no doubt than tarn-x or Brasso would make it look pretty and bring back it's original luster and charm. That would certainly instil a lot of warm and fuzzies and make me feel proud about the recycle effort, but I guess it gets to the unasked question. Is there any advantage of going through that effort other than cosmetic? That is the way I should have worded it the first time around.....my apologies....!!

Well, if the outer skin is tarnish, and RF propagates by 'skin effect' my guess is it would depend on the relative conductivities of copper vs tarnish.
I wonder if using a DC ohmmeter [being cautious not to break through to clean copper] to do a comparison would give results relevant at HF?

Topic: 19970 Message: 20002

underrated as meaning they can handle loads a LOT bigger than what they
say they are rated at.

I mean a Alliance U-110 handles that full sized TA-33 for over ten years
on top of a 50 foot tower.

The only trouble it even had was if it was very windy it would stall out
and not be able to turn it till the wind died down some. But that was
it, it never broke or anything and worked flawlessly for over a decade.
not bad for a rotor that cost like 20 bucks.

From: Siegfried Jackstien
Topic: 19970 Message: 20004

Sadly when my house burned down 4 years ago i lost my ham4/cd45 :-(
I mechanically made it a bit stronger (or better say a lot stronger)
Original in that rotor there were 8 balls on upper and 8 on the lower side
The space between them was hold to distance with a cage
Now after several years of use (I bought it used) there were some marks or
better say "holes" in the surface were the balls were running
The reason was that if you have only that low number then 2 balls on upper
and lower side act like a turning point or axle and only the rest of balls
(3 on each side) have to hold the bending force ...
Original diameter of the balls was 9.8mm
I opened the case and throw out everything from the bearing
I went to a local supplier were I could get steel balls with 10mm diameter
In a bag of 100 for only a few bucks
I needed 96 balls to make the rotor almost full (half a ball left as gap)
Before refilling I filed the surface a bit down to get rid of the marks or
holes ... the bigger diameter of the metric balls was just right to have
some material to file down to a smooth surface :-)
After refilling with the new balls and some good grease the rotor was
running smooth and could hold a lot bigger load
So for all others: open your rotor and see if the manufacturer only took a
few balls inside ... if that is the case you should throw the cage out and
fill the rotor with balls and some fresh grease

From: g4ldsqrp
Topic: 19970 Message: 20007

Depends on your location & pocket.

In some locations with minimum wind a TV rotator could be used & in others you need a beast!!
Go for one that can handle the wind load at mimimum of the Aerial(s) you want to stay up safely.
Check the local weather for max winds and dont forget that the aerial being in the clear and higher will get stronger wind gusts.

Chris

Topic: 19970 Message: 20009

Sigi, Again no offense meant and my reply wasn't directed to anyone in particular. You're correct about my German. My last name is German but I know only how to recognize it from hearing my German Grandmother calling me names when I misbehaved. The term rotor has been used through out the thread and elsewhere. I used it too until It was explained to me one day. Disk brakes use rotors but antenna rotators don't.

20011. Re: G5RV or Buckmaster Diapole...why are some bare wire or coated? Is one better?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-04 12:51:36 UTC
From: fred
Topic: 19986 Message: 20011

there is no difference in performance I have noticed . the only thing is that a wire with insulation seems to be electrically longer than bare wire and I had to make the insulated wire about 4 inches shorter on both sides to get it resonant . can't say about the G5RV or buckmaster antennas as I have never used them . I did look at getting the 7 band buckmaster OCF and decided not to after I read the warning about the balun .

20015. Questions about using schedule 40 black iron pipe for antenna mast

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-04 14:04:18 UTC
From: radio_wx1yz
Topic: 20015 Message: 20015

Hi all,

This is my first post to this group, so go easy with me please. :)

After about twenty years as a ham I am going to get my first HF rig this fall. I intend to use a LnR Precision end fed antenna with it.

I want to suspend the antenna between two masts made of schedule 40 black iron pipe. My plan is to have coupled three ten foot sections together and sitting in a five gallon bucket of Quikrete. The base should weigh about one hundred pounds. I'll guy it at the top and fifteen feet.

Would appreciate any thoughts, criticisms, experience.

Thanks and 73
Tom Gosse, WX1YZ

20016. Re: [ham-antennas] 6 METER ANTENNAS MOXON RECTANGLE EXCELLENT WIDE ANGLE BEAM

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-04 14:05:49 UTC
From: Prof. Arnaldo Coro Antich
Topic: 20012 Message: 20016

Amigos !
The MOXON Rectangle antenna is excellent for 6 meters band work.
It can be made easily, and has a very wide horizontal pattern coverage...
I ran one beaming to 160 degrees to work TEP from here, that should
be up again soon... No need for rotor because the minus 3dB pattern
points cover 140 degrees of acimut !!!
A lot of information about the Moxon Rectangle is available by just
typing Moxon Antenna on any Internet search engine...

Where do plan to operate ?
SSB and CW is below 50.300, The SSB Domestic Calling Freq is 50.125, The International calling Frequency is 50.110
Most activity is below 50.300
If you are into FM or moonbounce then I think the frequencies are higher

No beams? Then go dipole. 6 meter users use horizontally polarized antennas.

I just got a new rig with 6 meters this is a new band for me a i need a 6 meter antenna , is a dipole a good choice or is a jpole a better one, no beams because of cost of rotor and space . 73's w8jbv

It is the same here as it is always, the first question that must be asked is: do you want to
talk to "anyone" or someone or some place in particular. Both horizontal and vertical dipoles work
the same other than polarity and pattern shape.

The MOXON is a great antenna, I build one of these about a year ago and it was easy, cheap and best of all it worked great! Worked many, many grid sq. out west with just 10 watts and this ant.

Amigos !
The MOXON Rectangle antenna is excellent for 6 meters band work.
It can be made easily, and has a very wide horizontal pattern coverage...
I ran one beaming to 160 degrees to work TEP from here, that should
be up again soon... No need for rotor because the minus 3dB pattern
points cover 140 degrees of acimut !!!
A lot of information about the Moxon Rectangle is available by just
typing Moxon Antenna on any Internet search engine...

Galvanized may last longer than black. If it's anything like a bike lift
of pipe, if it's going to fail it will be at the threaded
couplings--consider having it welded?

My local Ace Hardware has a telescoping 30-foot mast with guy rings
already on it, purpose-made for antenna work...

Topic: 20015 Message: 20023

I don’t see any reason why it won’t work but schedule 80 might be better or get 3 steel 10’ antenna masts that just butt into each other. Radio Shack makes them in either 5’ and 10’. They have a little tit on the inside of the poles on one end and a slot on the other end. They don’t turn once mated together. At 30’ they will have to be guyed if you put anything heavy on them like say a 15’ vertical 440 MHz antenna and you have a lot of wind like I have.

Here are some web pages on PVC masts.

http://forums.radioreference.com/scanner-receiver-antennas/101043-using-pvc-antenna-mast.html

http://forums.qrz.com/showthread.php?286123-35-PVC-Antenna-Mast-Tower-Ideas

http://forums.radioreference.com/scanner-receiver-antennas/7590-ground-antenna-mast.html

http://forums.radioreference.com/scanner-receiver-antennas/163459-pvc-antenna-mast-vs-steel.html

I just looked up PVC antenna masts in google. Got a lot of sites to look at but the main thing I saw was, no ground and they will not hold up anything heavy. If its just holding up a dipole it might work but I would go schedule 80 to be safe.

Hi all,

This is my first post to this group, so go easy with me please. :)

After about twenty years as a ham I am going to get my first HF rig this fall. I intend to use a LnR Precision end fed antenna with it.

I want to suspend the antenna between two masts made of schedule 40 black iron pipe. My plan is to have coupled three ten foot sections together and sitting in a five gallon bucket of Quikrete. The base should weigh about one hundred pounds. I'll guy it at the top and fifteen feet.

Would appreciate any thoughts, criticisms, experience.

Thanks and 73

I would go with steel pipe and telescope them, not black iron or the S80 PVC.

You can find pictures and drawings of my two simple tilt masts at
http://s1102.photobucket.com/albums/g453/KD0ZZ/

The small one is at only 20ft(two 1.5 rigid conduit) and the larger about 45ft, steel pipe. The small one has also been used with only one 10ft section for a 20M cage vertical and also a four band vertical.

A ham friend used this material for a 35-foot mast. As he was raising it, it snapped at every coupling. Black pipe is NOT recommended.

Look to nested steel tubing. You can raise the set, estabilish the guying, slide the next section up, lock, establish guying if any, raise the next section up, lock, establish the guying, etc.

There is also a poster to this group who has pix of tilt-up steel tubing masts. Check them out.

Just stay clear of black iron pipe. It was not designed for making masts, and does not have the needed strength in any direction not along the axis of the pipe. This stuff was designed to lay in or on the ground, not be elevated.

Topic: 20015 Message: 20027

I work for an outfit that sells both black and galvanized pipe. As already been said, black pipe will rust and as galvanized pipe the junctions will be at most 1 1/2 to 2", making them the weakest points. Also, as has already been said, I agree that push-up is best. Make sure guys are as non metalic as possible so as not to affect the performance of your antenna. Hope my 2¢ helps, welcome to the group, and welcome to hf. You will enjoy many good contacts, and this group is extreamly glad to help you, no matter how trivial.
